- Cryptography and Network captures,
- D4 passiveSSL Collection,
- Leveraging OpenPGP metedata,
- Checking for weak crypto.

# Cryptography 101

- **Plaintext** P: Text in clear,
- **Encryption** E: Process of disguising the plaintext to hide its content,
- **Ciphertext** C: Result of the Encryption process,
- **Decryption** D: Process of reverting encryption, transforming C into P,
- **Encryption Key** EK: Key to encrypt P into C,
- **Decryption Key** DK: Key to decrypt C into P,
- **Cryptanalysis**: Analysis of C to recover P without knowing K.

- **Confidentiality** : Ensure the secrecy of the message except for the **intended** recipient,
- **Authentication** : Proving a party's identity,
- **Integrity** : Verifying that data transmitted were not altered,
- **Non-repudiation** : Proving that the sender sent a given message.

- **In-transit encryption:** protects data while it is transferred from one machine to another,
- **At-rest encryption:** protects data stored on one machine.

*It [cipher] should not require secrecy, and it should not be a problem if it falls into enemy hands.*

**There is no security in obscurity.**

**Black Box** - Attackers may only see inputs / outputs:

- **Ciphertext-Only Attackers (COA)**: see only the ciphertext,
- **Known-Plaintext Attackers (KPA)**: see ciphertext and plaintext,
- **Chosen-Plaintext Attacker (CPA)**: encrypt plaintext, and see ciphertext,
- **Chosen-Ciphertext Attackers (CCA)**: encrypt plaintext, decrypt ciphertext.

**Grey Box** - Attackers see cipher's implementation:

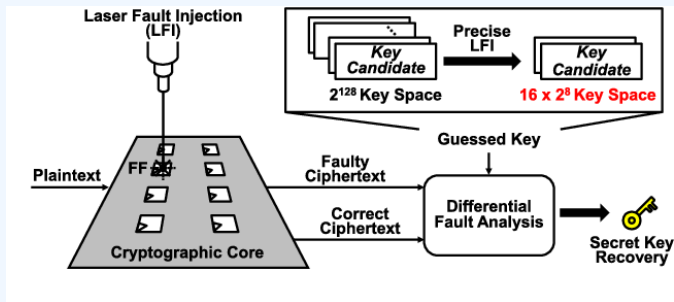

- **Side-Channel Attacks:** study the behavior of the implementation, eg. **timing attacks** <sup>1</sup>:
  - ▶ Osvik, Shamir, Tromer [OSTo6]: Recover AES-256 secret key of Linux's dmccrypt in just 65 ms
  - ▶ AlFardan, Paterson [AFP13]: "Lucky13" recovers plaintext of CBC-mode encryption in pretty much all TLS implementations
  - ▶ Yarom, Falkner [YF14]: Attack against RSA-2048 in GnuPG 1.4.13: "On average, the attack is able to recover 96.7% of the bits of the secret key by observing a single signature or decryption round."
  - ▶ Benger, van de Pol, Smart, Yarom [BvdPSY14]: "reasonable level of success in recovering the secret key" for OpenSSL ECDSA using secp256k1 "with as little as 200 signatures"

## Most recent timing attack: **TPM-fail** [24420]

We discovered timing leakage on Intel firmware-based TPM (fTPM) as well as in STMicroelectronics' TPM chip. Both exhibit secret-dependent execution times during cryptographic signature generation. While the key should remain safely inside the TPM hardware, we show how this information allows an attacker to recover 256-bit private keys from digital signature schemes based on elliptic curves.

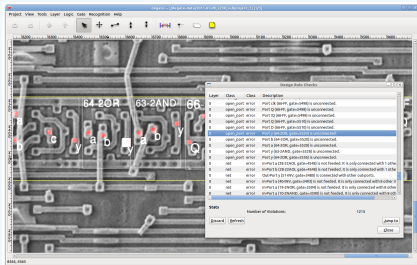

## ■ Invasive Attacks:

- ▶ injecting faults [MFS<sup>+</sup>18],

# ATTACKERS MODEL V

- ▶ decapping chips<sup>2</sup>, reverse engineering<sup>3 4</sup>, etc.

<sup>1</sup><https://cryptojedi.org/peter/data/croatia-20160610.pdf>

<sup>2</sup><https://siliconpron.org/wiki/doku.php?id=decap:start>

<sup>3</sup><http://siliconzoo.org>

<sup>4</sup><http://degate.org>

- **Indistinguishability (IND)**: Ciphertexts should be indistinguishable from random strings,
- **Non-Malleability (MD)**: “Given a ciphertext  $C_1 = E(K, P_1)$ , it should be impossible to create another ciphertext,  $C_2$ , whose corresponding plaintext,  $P_2$ , is related to  $P_1$  in a meaningful way.”

Semantic Security (IND-CPA) is the most important security feature:

- Ciphertexts should be different when encryption is performed twice on the same plaintext,
- To achieve this, randomness is introduced into encryption / decryption:
  - ▶  $C = E(P, K, R)$
  - ▶  $P = D(C, K, R)$

For instance AES-ECB is not semantically secure - An attacker can build a codebook to crack it. No Semantic Security without randomness

Random Number Generator:

Pseudo Random Number Generator:

RSA 2048 is roughly 100 bits security.

Some attacks requires less than CCA / CPA:

- Side Channel attacks as for instance Padding Oracle (Vaudenay Attacks)

## Encryption and Law Enforcement

- In the arms race between cryptographers and crypto-analysts. In terms of practical breaks, cryptographers are miles ahead.
- In a society that is ever more depending on the correct functioning of electronic communication services, technical protection of these service is mandatory,
- In the face of serious crimes, law enforcement may lawfully intrude privacy or break into security mechanisms of electronic communication,
- **proportionality** - collateral damages (class breaks)
- Resolving the encryption dilemma: collect and share best practices to circumvent encryption.

*Any effort to reveal an unencrypted version of a target's data that has been concealed by encryption.*

## ■ Try to get the key:

### ▶ Find the key:

- physical searches for keys,
- password managers,
- web browser password database,
- in-memory copy of the key in computer's HDD / RAM.
- seize the key (keylogger).

### ▶ Guess the key:

- Whereas encryption keys are usually too hard to guess (eg. 128bits security is  $2^{128}$  trials (universe is  $2^{88}$  ns old)),
- passphrases are usually shorter to be memorizable, and are linked to the key,
- some systems have limitations on sorts of passwords (eg. 4/6 digits banking application),
- educated guess on the password from context,

# ENCRYPTION WORKAROUNDS [KS17] II

- educated guess from owner's other passwords,
- dictionaries and password generation rules <sup>(5)</sup>.
- Offline / online attacks (eg. 13 digits pw: 25.000 on an iphone VS matter of minutes offline),
- + beware devices protection when online (eg. iphone erase on repeated failures).

## ► Compel the key:

## ■ Try to access the PlainText without the key:

### ▶ Exploit a Flaw:

- Weakness in the algorithm (more on that later),
- weakness in the random-number generator (more on that later),
- weakness in the implementation,
- bugs (eg. Gordon's exploit on android in 2015<sup>6</sup>),
- backdoors (eg. NSA NOBUS -Bullrun program- Dual EC-DRBG [BLN15])

### ▶ Access PlainText when in use:

- Access live system memory,
- especially useful against Full Disk Encryption,
- Seize device while in use,
- remotely hack the device,
- "Network Investigative Technique" (eg. Playpen case against tor).

▶ **Locate a PlainText copy:**

- Avoid encryption entirely,
- cloud providers (eg. emails),
- remote cloud storage (eg. iCloud),

**Takeaways:**

- **No workaround works every time:** the fact that a target used encryption does not mean that the investigation is over.
- **some workarounds are expensive:** exploiting.
- **expertise may be have to be found outside of the governments:** vendors' assistance?

Technically, we can retain that crypto-systems have weaknesses:

- key generation,
- key length,
- key distribution,
- key storage,
- how users enter keys into the crypto-system,
- weakness in the algorithm itself / implementation,
- system / computer running the algorithm,
- crypto system used in different points in time,
- **users.**

## **Cryptography and Network captures**

## **D4 passiveSSL Collection**

## Leveraging OpenPGP metadata

## Checking for weak crypto

IoT devices **are often the weakest devices** on a network:

- Usually the result of cheap engineering,
- sloppy patching cycles,
- sometimes forgotten—not monitored,
- few hardening features enabled.

**We feel a bit safer when they use TLS, but should we?**

---

<sup>7</sup><https://github.com/d4-project/snake-oil-crypto>

**Keep** a log of links between:

- x509 certificates,
- ports,
- IP address,
- client (ja3),
- server (ja3s),

*“JA3 is a method for creating SSL/TLS client fingerprints that should be easy to produce on any platform and can be easily shared for threat intelligence.”<sup>8</sup>*

**Pivot** on additional data points during Incident Response

---

<sup>8</sup><https://github.com/salesforce/ja3>

**Collect** and **store** x509 certificates and TLS sessions:

- Public keys type and size,
- moduli and public exponents,
- curves parameters.

**Detect** anti patterns in crypto:

- Moduli that share one prime factor,
- Moduli that share both prime factors, or private exponents,
- Small factors,
- Nonces reuse / common preffix or suffix, etc.

**Focus on low hanging fruits that appeal to attackers**

Researchers have shown that several devices generated their keypairs at boot time without enough entropy<sup>9</sup>:

```
prng.seed(seed)
p = prng.generate_random_prime()
// prng.add_entropy()
q = prng.generate_random_prime()
n = p*q
```

Given  $n=pq$  and  $n' = pq'$  it is trivial to recover the shared  $p$  by computing their **Greatest Common Divisor (GCD)**, and therefore **both private keys**<sup>10</sup>.

---

<sup>9</sup>Bernstein, Heninger, and Lange: <http://facthacks.cr.yp.to/>

<sup>10</sup><http://www.loyalty.org/~schoen/rsa/>

In Snake-Oil-Crypto we compute GCD<sup>11</sup> between:

- between certificates having the same issuer,
- between certificates having the same subject,
- on keys collected from various sources (PassiveSSL, Certificate Transparency, shodan, censys, etc.),

**“Check all the keys that we know of for vendor X”**

---

<sup>11</sup>using Bernstein's Batch GCD algorithm

The MISP feed:

- **Allows** for checking automatic checking by an IDS on hashed values,
- **contains** thousands on broken keys from a dozen of vendors,
- **will be accessible upon request (info@circl.lu).**

In the future:

- **Automatic** the vendor checks by performing TF-IDF on x509's subjects,
- **automatic** vendors notification.

- ✓ sensor-d4-tls-fingerprinting <sup>12</sup>: **Extracts** and **fingerprints** certificates, and **computes** TLSH fuzzy hash.
- ✓ analyzer-d4-passivessl <sup>13</sup>: **Stores** Certificates / PK details in a PostgreSQL DB.
- snake-oil-crypto <sup>14</sup>: **Performs** crypto checks, push results in MISP for notification
- lookup-d4-passivessl <sup>15</sup>: **Exposes** the DB through a public REST API.
